Sequence-structure relationships in RNA

# Sequence-Structure Map of RNA

- 1 *Redundancy*: Many more sequences than structures
- 2 *Sensitivity*: Small changes in the sequences may lead to large changes in the structure
- 3 *Neutrality*: A substantial fraction of mutations does not alter the structure.

Implications:

- 1 *Neutral Networks*:  $S(\psi)$  forms a connected “percolating” network in sequence space for all “common” structures.
  - 2 *Mutual Accessibility*: The neutral networks of any two structures almost touch each other somewhere in sequence space.
- RNA sequence evolve drift-like while maintaining secondary structure
  - Substitution pattern reflects selective constraints on the structure

# Implementations

Several programs are available that implement simple inverse folding:

- `RNAinverse` (Hofacker *et al.* 1994)  
unbiased search using adaptive walks and a simple hierarchical problem decomposition
- `RNAdesigner` (Andronescu 2004)  
Uses sequence bias in paired/unpaired regions, more sophisticated decomposition to speed up search
- `INFO-RNA` (Busch & Back 2006)  
Uses a sequence with minimal energy for the target structure as starting point (strong sequence bias)
- `NUPACK` (Zadeh, Wolf, Pierce 2011)  
Allows design of multi-strand structures
- `RNAiFOLD` (Garcia-Martin, Clote, Dotu 2013)  
uses constraint programming or a large neighborhood search heuristic

# One Sequence, Two target Structures

Schultes, EA & Bartel, DP; Science (2000), 289:448-452

# Design of Artificial Riboswitches

- Riboswitches are a convenient gadget in synthetic biology
- Task: combine ligand-specific sensor with an effector (i.e., some form of a regulatory element)
- Question: to what extent is this really modular?
- Idea: use RNA structure prediction to model the interplay of sensor and effector

# Riboswitches: Regulators of Gene Expression

Transcriptional *versus* translational riboswitch

# Design Idea

Goal: a theophylline triggered on-switch

# Essence of the Multistable Design Problem

- Design a sequence that *compatible* with not just one but *several* target structures
- Each target should be almost a ground state
- **Questions:**
  - When can this be solved?
  - How can we include ligand specificity
- First step: generate sequences that are compatible with all design goals.
- 2nd step: optimize the sequences toward the design goal(s)

# Bi-Stable Structures

Given two structures  $\mathcal{S}_1$   $\mathcal{S}_2$ , are there sequences compatible to both?

**intersection theorem:**

$$\mathbf{C}[\mathcal{S}_1] \cap \mathbf{C}[\mathcal{S}_2] \neq \emptyset$$

**Proof:** Dependency graph decomposes into paths and cycles of even length

the alternating sequence  $AUAUAU \dots$  is compatible with each path and cycle.

# Examples of bistable structures

$$\Xi(x) = E(x, \Omega_1) + E(x, \Omega_2) - 2G(x) + \xi (E(x, \Omega_1) - E(x, \Omega_2))^2$$

# Multi-Stable Structures

Generalization to multiple Targets:

**Theorem.** There is a sequence satisfying each secondary structure constraints  $S_1, S_2, \dots, S_M$  if and only if the overlap graph  $S_1 \cup S_2 \cup \dots \cup S_M$  is bipartite.

(.) .. (.....) . (.....) .  
 (.....) (.....) .....  
 (.....) (.....) .....  
 (.. (.....) .....)  
 (.. (.....) (.....)) .....  
 ... (..... (.....) .)

# Solving Multi-Constraint Design Problems

- one possibility: constraint programming [Dotu's work]
- stochastic heuristics
  - Complex search space. Only  $\mathbf{C} := \bigcap_{i=1}^M \mathbf{C}(\Omega_i)$  allowed
  - How to choose a good (fair) starting position?  
simple for  $M = 2$ : constraints are path and cycles. Simple recursions to sample uniformly from  $\mathbf{C}$
  - Difficult for  $M > 2$ : need more complex decompositions of graphs

# How to sample uniformly?

Use the overlap graph: it defines the dependence structure of nucleotides.

- Zeroth Step: connected components are independently sampled.
- First Step: block decomposition of the overlap graph.  
Color every block separately with fixed colors at the cut points

- Second Step: Color Blocks by Dynamic Programming

# Coloring dense blocks: Ear decomposition

## ear decomposition

complement graph with attachment vertices

- dynamic programming approach to count colorings with given color combinations at the attachment vertices.
- memory exponential in the maximum number of attachment vertices  $\alpha$ , CPU time in the maximum size of the union of attachment vertices in consecutive steps  $\beta$

# A design for the SV11 switch

# Back to the Theophylline Switch

Goal: a theophylline triggered on-switch

Activities of optimized constructs

# Working in Tandem ...

# ... works even better

# A more principled way to include ligand binding

- Known/measured binding energy  $-\varepsilon$  of the ligand to a particular structural motif  $\Psi$  necessary for binding.
- without ligand: we want structural feature  $\Omega$
- with ligand: we want structural feature  $\Psi$
- Compute the partition function  $Z[\Psi]$  over all structures with feature  $\Psi$ .

Partition function over structures without feature  $\Psi$  is

$$Z[\neg\Psi] := (Z - Z[\Psi])/Z.$$

- Binding distorts the ensemble of structure when the ligand is present:  $Z_L = Z[\neg\Psi] + Z[\Psi] \exp(-\varepsilon)$
- Objectives
  - without ligand:  $p_0(\Omega) := Z[\Omega]/Z \rightarrow \max$  and  $p_0(\Psi)$  should be small
  - with ligand:  $p_L(\Psi) := Z[\Psi] \exp(-\varepsilon)/Z_L \rightarrow \max$  and  $p_L(\Omega)$  should be small.  
...easy if  $\Psi$  and  $\Omega$  are mutually exclusive, otherwise we also need the partition function  $Z(\Omega \wedge \Psi)$ .

# Using Constraints ...

Modified folding algorithms that scores certain structures differently  
 $Z\{\psi; e\}$  scores a (set of) pattern(s)  $\psi$  (in practice e.g. the loop forming the binding pocket) with bonus energies  $e$

Key relationship:

$$\frac{[RNA \cdot L]}{[RNA][L]} = K = \frac{Z\{\psi; e\}}{Zz_L}$$

Set  $z_L = 1$  for a small molecular ligand and gauge the binding energies accordingly.

$$Z\{\psi; e\} \approx Z[\neg\Psi] + Z[\Psi] \exp(-\varepsilon)$$

in the more general model with (soft) constraints we may include a more elaborate parametrization that includes e.g. a set of variant binding site structures ...

Details of the theory (and implementations) are still being developed ...
