Why Quantum Dynamics?

Why Quantum dynamics?

GS adiabatic dynamics (BO vs. CP)

BO \( M_i \ddot{R}_i(t) = -\nabla \min_{\rho} E_{KS}(\{\phi_i[\rho]\}) \)

CP \( \mu_i |\dddot{\phi}_i(t)\rangle = -\frac{\delta}{\delta |\phi_i\rangle} E_{KS}(\{\phi_i(\mathbf{r})\}) + \frac{\delta}{\delta |\phi_i\rangle} \{\text{constr.}\} \)

\( M_i \ddot{R}_i(t) = -\nabla E_{KS}(\{\phi_i(t)\}) \)

ES nonadiabatic quantum dynamics

- We cannot get rid of electrons
- Nuclei keep some QM flavor
- Accuracy is an issue
- Size can be large (diffuse excitons)
+ Time scales are usually short (< ps)
Nonadiabatic effects requires quantum nuclear dynamics

The nuclear dynamics cannot be described by a single classical trajectory (like in the ground state -adiabatically separated- case)
Why trajectory-based approaches?

**W1** In “conventional” nuclear wavepacket propagation potential energy surfaces are needed.

**W2** Difficulty to obtain and fit potential energy surfaces for large molecules.

**W3** Nuclear wavepacket dynamics is very expensive for large systems (6 degrees of freedom, 30 for MCTDH). Bad scaling.

**T1** Trajectory based approaches can be run *on-the-fly* (no need to parametrize potential energy surfaces).

**T2** Can handle large molecules in the full (unconstraint) configuration space.

**T3** They offer a good *compromise* between accuracy and computational effort.

TDDFT in mixed quantum-classical dynamics
Mixed quantum-classical dynamics

Starting point

The starting point is the molecular time-dependent Schrödinger equation:

\[ \hat{H}\psi(r, R, t) = i\hbar \frac{\partial}{\partial t} \psi(r, R, t) \]

where \( \hat{H} \) is the molecular time-independent Hamiltonian and \( \psi(r, R, t) \) the total wavefunction (nuclear + electronic) of our system.

In mixed quantum-classical dynamics the nuclear dynamics is described by a swarm of classical trajectories (taking a "partial" limit \( \hbar \to 0 \) for the nuclear wf).

In this lecture we will discuss two main approximate solutions based on the following Ansätze for the total wavefunction:

- Born-Huang Ansatz:
  \[ \psi(r, R, t) \xrightarrow{\text{Born-Huang}} \sum_{j} \phi_j(r; R) \omega_j(R, t) \]

- Ehrenfest Ansatz:
  \[ \psi(r, R, t) \xrightarrow{\text{Ehrenfest}} \Phi(r, t) \Omega(R, t) \exp \left[ \frac{i}{\hbar} \int_{t_0}^{t} E_{el}(t') dt' \right] \]

- Exact Factorization Ansatz:
  \[ \psi(r, R, t) \xrightarrow{\text{Exact Factorization}} \Phi_R(r, t) \Omega(R, t); \quad \text{with} \quad \int dr \Phi_R(r, t) = 1, \quad \forall R. \]
Tarjectory-based quantum and mixed QM-CL solutions

We can “derive” the following trajectory-based solutions:

- **Nonadiabatic Ehrenfest dynamics**

- **Adiabatic Born-Oppenheimer MD equations**

- **Nonadiabatic Bohmian Dynamics (NABDY)**

- **Nonadiabatic Trajectory Surface Hopping (TSH) dynamics**

- **Time dependent potential energy surface approach**
  based on the exact decomposition: $\Psi(r, R, t) = \Omega(R, t)\Phi(r, t)$.
Inserting this representation of the total wavefunction into the molecular td Schrödinger equation and multiplying from the left-hand side by $\Omega^*(R, t)$ and integrating over $R$ we get

$$i\hbar \frac{\partial \Phi(r, t)}{\partial t} = -\frac{\hbar^2}{2m_e} \sum_i \nabla_i^2 \Phi(r, t) + \left[ \int dR \Omega^*(R, t) \hat{V}(r, R) \Omega(R, t) \right] \Phi(r, t)$$

where $\hat{V}(r, R) = \sum_{i<j} \frac{e^2}{|r_i-r_j|} - \sum_{\gamma,i} \frac{e^2Z_\gamma}{|R_\gamma-r_i|}$.

In a similar way, multiplying by $\Phi^*(r, t)$ and integrating over $r$ we obtain

$$i\hbar \frac{\partial \Omega(R, t)}{\partial t} = -\frac{\hbar^2}{2} \sum_{\gamma} M_{\gamma}^{-1} \nabla_{\gamma}^2 \Omega(R, t) + \left[ \int dr \Phi^*(r, t) \hat{H}_{el} \Phi(r, t) \right] \Omega(R, t)$$

Conservation of energy has also to be imposed through the condition that $d \langle \hat{H} \rangle / dt \equiv 0$.

Note that both the electronic and nuclear parts evolve according to an average potential generated by the other component (in square brackets). These average potentials are time-dependent and are responsible for the feedback interaction between the electronic and nuclear components.
We start from the polar representation of the nuclear wavefunction

$$\Omega(R, t) = A(R, t) \exp \left[ \frac{i}{\hbar} S(R, t) \right]$$

where the amplitude $A(R, t)$ and the phase $S(R, t)/\hbar$ are real functions.

Inserting this representation for $\Omega(R, t)$ and separating the real and the imaginary parts one gets for the phase $S$ in the classical limit $\hbar \to 0$

$$\frac{\partial S}{\partial t} = -\frac{1}{2} \sum_{\gamma} M_{\gamma}^{-1} \left( \nabla_{\gamma} S \right)^2 - \left[ \int dr \, \Phi^*(r, t) \hat{H}_{el}(r, R) \Phi(r, t) \right]$$

This has the form of the "Hamilton-Jacobi" (HJ) equation of classical mechanics, which establishes a relation between the partial differential equation for $S(R, t)$ in configuration space and the trajectories of the corresponding (quantum) mechanical systems.
Ehrenfest dynamics - the nuclear equation

\[ \frac{\partial S}{\partial t} = -\frac{1}{2} \sum_\gamma M_\gamma^{-1} (\nabla_\gamma S)^2 - \left[ \int dr \Phi^*(r, t) \hat{H}_{el}(r, R) \Phi(r, t) \right] \]

Instead of solving the field equation for \( S(R, t) \), find the equation of motion for the corresponding trajectories (characteristics).
The identification of \( S(R, t) \) with the "classical" action, defines a point-particle dynamics with Hamiltonian, \( H_{cl} \) and momenta

\[
P = \nabla_R S(R).
\]

The solutions of this Hamiltonian system are curves (characteristics) in the \((R, t)\)-space, which are extrema of the action \( S(R, t) \) for given initial conditions \( R(t_0) \) and \( P(t_0) = \nabla_R S(R)|_{R(t_0)} \). Newton-like equation for the nuclear trajectories corresponding to the HJ equation

\[
\frac{dP_\gamma}{dt} = -\nabla_\gamma \left[ \int dr \ Phi^*(r, t) \hat{H}_{el}(r, R) \Phi(r, t) \right]
\]

Ehrenfest dynamics

\[
i\hbar \frac{\partial \Phi(r; R, t)}{\partial t} = \hat{H}_{el}(r, R) \Phi(r; R, t)
\]

\[
M_l \ddot{R}_l = -\nabla_l \langle \hat{H}_{el}(r, R) \rangle
\]
The identification of $S(\mathbf{R}, t)$ with the "classical" action, defines a point-particle dynamics with Hamiltonian, $H_{cl}$ and momenta

$$\mathbf{P} = \nabla_{\mathbf{R}} S(\mathbf{R}).$$

The solutions of this Hamiltonian system are curves \textit{(characteristics)} in the $(\mathbf{R}, t)$-space, which are extrema of the action $S(\mathbf{R}, t)$ for given initial conditions $\mathbf{R}(t_0)$ and $\mathbf{P}(t_0) = \nabla_{\mathbf{R}} S(\mathbf{R})|_{R(t_0)}$. Newton-like equation for the nuclear trajectories corresponding to the HJ equation

$$\frac{d\mathbf{P}_\gamma}{dt} = -\nabla \gamma \left[ \int d\mathbf{r} \; \Phi^*(\mathbf{r}, t) \hat{\mathcal{H}}_{el}(\mathbf{r}, \mathbf{R}) \Phi(\mathbf{r}, t) \right]$$

\textbf{Ehrenfest dynamics - Densityfunctionalization ($\phi_k$: KS orbitals)}

$$i\hbar \frac{\partial}{\partial t} \phi_k(\mathbf{r}, t) = -\frac{1}{2m_e} \nabla^2 \phi_k(\mathbf{r}, t) + v_{\text{eff}}[\rho, \Phi_0](\mathbf{r}, t) \phi_k(\mathbf{r}, t)$$

$$M_I \dddot{\mathbf{R}}_I = -\nabla I E[\rho(\mathbf{r}, t)]$$
Ehrenfest dynamics

\[ i\hbar \frac{\partial}{\partial t} \phi_k(r, t) = -\frac{1}{2m_e} \nabla_r^2 \phi_k(r, t) + v_{\text{eff}}[\rho, \Phi_0](r, t) \phi_k(r, t) \]

\[ M_l \ddot{R}_l = -\nabla_l \langle \hat{H}_{\text{el}}(r; R) \rangle \]
Ehrenfest dynamics and mixing of electronic states

Ehrenfest dynamics

\[ i\hbar \frac{\partial \Phi(r; R, t)}{\partial t} = \hat{H}_{el}(r; R)\Phi(r; R, t) \]
\[ M_I \ddot{R}_I = -\nabla_I \langle \hat{H}_{el}(r; R) \rangle \]

Consider the following expansion of \( \Phi(r; R, t) \) in the \textit{static} basis of electronic wavefunctions \( \{\Phi_k(r; R)\} \)

\[ \Phi(r; R, t) = \sum_{k=0}^{\infty} c_k(t)\Phi_k(r; R) \]

The time-dependency is now on the set of coefficients \( \{c_k(t)\} \) \(|c_k(t)|^2\) is the population of state \( k \). Inserting in the Ehrenfest’s equations...
Ehrenfest dynamics and mixing of electronic states

Ehrenfest dynamics

\[ i\hbar \dot{c}_k(t) = c_k(t)E_{el}^k - i\hbar \sum_j c_j(t)D_{kj} \]

\[ M_I \ddot{\mathbf{R}}_I = -\nabla_I \sum_{k=0}^{\infty} |c_k(t)|^2 E_{el}^k \]

where

\[ D_{kj} = \langle \Phi_k | \frac{\partial}{\partial t} | \Phi_j \rangle = \langle \Phi_k | \frac{\partial \mathbf{R}}{\partial t} \frac{\partial}{\partial \mathbf{R}} | \Phi_j \rangle = \dot{\mathbf{R}} \langle \Phi_k | \nabla | \Phi_j \rangle = \dot{\mathbf{R}} \cdot \mathbf{d}_{kj} \]

Thus we incorporate directly nonadiabatic effects.
Ehrenfest dynamics: the mean-field potential

\[ i\hbar \dot{c}_k(t) = c_k(t)E^e_k - i\hbar \sum_j c_j(t)D_{kj} \]

\[ M_l \ddot{R}_l = -\nabla_l \sum_{k=0}^{\infty} |c_k(t)|^2 E^e_k \]
Tarjectory-based quantum and mixed QM-CL solutions

We can “derive” the following trajectory-based solutions:

- **Nonadiabatic Ehrenfest dynamics dynamics**

- **Adiabatic Born-Oppenheimer MD equations**

- **Nonadiabatic Bohmian Dynamics (NABDY)**

- **Nonadiabatic Trajectory Surface Hopping (TSH) dynamics**

- **Time dependent potential energy surface approach**
  based on the exact decomposition: \( \Psi(\mathbf{r}, \mathbf{R}, t) = \Omega(\mathbf{R}, t)\Phi(\mathbf{r}, t) \).
In this equation, \( \{ \Phi_j(r; R) \} \) describes a complete basis of electronic states solution of the time-independent Schrödinger equation:

\[
\hat{H}_{el}(r; R)\Phi_j(r; R) = E_{el,j}(R)\Phi_j(r; R)
\]

\( R \) is taken as a parameter.

Eigenfunctions of \( \hat{H}_{el}(r; R) \) are considered to be orthonormal, i.e. \( \langle \Phi_j | \Phi_i \rangle = \delta_{ij} \).
Electrons are static. Use your favourite electronic structure method.

For the nuclei, insert this Ansatz into the molecular time-dependent Schrödinger equation

\[
\hat{H}\Psi(r, R, t) = i\hbar\frac{\partial}{\partial t}\Psi(r, R, t)
\]

After left multiplication by \(\Phi_k^*(r; R)\) and integration over \(r\), we obtain the following equation (we used \(\langle \Phi_j | \Phi_i \rangle = \delta_{ij}\)) :

\[
\left[ -\sum_i \frac{\hbar^2}{2M_i} \nabla_i^2 + E_{el,k}(R) \right] \Omega_k(R, t) + \sum_j D_{kj} \Omega_j(R, t) = i\hbar \frac{\partial}{\partial t} \Omega_k(R, t)
\]
Born-Oppenheimer approximation

\[
\left[ -\sum_I \frac{\hbar^2}{2M_I} \nabla^2_I + E_{el,k}(R) \right] \Omega_k(R, t) + \sum_j D_{kj} \Omega_j(R, t) = i\hbar \frac{\partial}{\partial t} \Omega_k(R, t)
\]

- Equation for the nuclear “wavepacket”, \( \Omega(R, t) \), dynamics.
- \( E_{el,k}(R) \) represents a potential energy surface for the nuclei.

**Important additional term :** \( D_{kj} \) ! NONADIABATIC COUPLING TERMS

\[
D_{kj} = \int \Phi^*_k(r; R) \left[ \sum_I \frac{\hbar^2}{2M_I} \nabla^2_I \right] \Phi_j(r; R) dr + \sum_I \frac{1}{M_I} \left\{ \int \Phi^*_k(r; R) \left[ -i\hbar \nabla_I \right] \Phi_j(r; R) dr \right\} \left[ -i\hbar \nabla_I \right]
\]
Mixed quantum-classical dynamics

Adiabatic Born-Oppenheimer dynamics

**Born-Oppenheimer approximation**

\[
D_{kj} = \int \Phi_k^*(r; R) \left[ \sum_l \frac{\hbar^2}{2M_l} \nabla^2_l \right] \Phi_j(r; R) dr \\
+ \sum_l \frac{1}{M_l} \left\{ \int \Phi_k^*(r; R) \left[ -i\hbar \nabla_l \right] \Phi_j(r; R) dr \right\} \left[ -i\hbar \nabla_l \right]
\]

If we neglect all the \( D_{kj} \) terms (diagonal and off-diagonal), we have the **Born-Oppenheimer approximation**.

\[
\left[ -\sum_l \frac{\hbar^2}{2M_l} \nabla^2_l + E_{el,k}(R) \right] \Omega_k(R, t) = i\hbar \frac{\partial}{\partial t} \Omega_k(R, t)
\]

*Mainly for ground state dynamics or for dynamics on states that do not couple with others.* (Back to nonadiabatic dynamics later).
Using a polar expansion for $\Omega_k(R, t)$, we may find a way to obtain classical equation of motions for the nuclei.

$$\Omega_k(R, t) = A_k(R, t) \exp \left( \frac{i}{\hbar} S_k(R, t) \right).$$

$A_k(R, t)$ represents an amplitude and $S_k(R, t)/\hbar$ a phase.

Further: insert the polar representation into the equation above, do some algebra, and separate real and imaginary part, we obtain an interesting set of equations:
Born-Oppenheimer approximation: the nuclear trajectories

\[ \frac{\partial S_k}{\partial t} = \frac{\hbar^2}{2} \sum_l M_l^{-1} \frac{\nabla^2 A_k}{A_k} - \frac{1}{2} \sum_l M_l^{-1} (\nabla_l S_k)^2 - E_k \]

\[ \frac{\partial A_k}{\partial t} = -\sum_l M_l^{-1} \nabla_l A_k \nabla_l S_k - \frac{1}{2} \sum_l M_l^{-1} A_k \nabla_l^2 S_k \]

Dependences of the functions \( S \) and \( A \) are omitted for clarity (\( k \) is an index for the electronic state; in principle there is only one state in the adiabatic case).

We have now a time-dependent equation for both the amplitude and the phase. Since we are in the adiabatic case there is only one PES and the second equation becomes trivially a diffusion continuity equation.

The nuclear dynamics is derived from the real part \( \frac{\partial S_k}{\partial t} \). This equation has again the form of a classical Hamilton-Jacobi equation.
Mixed quantum-classical dynamics

Adiabatic Born-Oppenheimer dynamics

Born-Oppenheimer approximation: the nuclear trajectories

\[
\frac{\partial S_k}{\partial t} = \frac{\hbar^2}{2} \sum_{l} M_l^{-1} \frac{\nabla^2 A_k}{A_k} - \frac{1}{2} \sum_{l} M_l^{-1} (\nabla_l S_k)^2 - E_k
\]

\[
\frac{\partial A_k}{\partial t} = - \sum_{l} M_l^{-1} \nabla_l A_k \nabla_l S_k - \frac{1}{2} \sum_{l} M_l^{-1} A_k \nabla_l^2 S_k
\]

Instead of solving the field equation for \( S(R, t) \), find the equation of motion for the corresponding trajectories (characteristics).

TDDFT in mixed quantum-classical dynamics
Born-Oppenheimer approximation: the nuclear trajectories

\[ \frac{\partial S_k}{\partial t} = \frac{\hbar^2}{2} \sum_l M_l^{-1} \frac{\nabla^2 A_k}{A_k} - \frac{1}{2} \sum_l M_l^{-1} (\nabla_l S_k)^2 - E_k \]

The classical limit is obtained by taking\(^1\): \( \hbar \rightarrow 0 \)

\[ \frac{\partial S_k}{\partial t} = -\frac{1}{2} \sum_l M_l^{-1} (\nabla_l S_k)^2 - E_k \]

These are the classical Hamilton-Jacobi equation and \( S \) is the classical action related to a particle.

\[ S(t) = \int_{t_0}^t L(t') dt' = \int_{t_0}^t [E_{\text{kin}}(t') - E_{\text{pot}}(t')] dt' \]

The momentum of a particle \( l \) is related to

\[ \nabla_l S = p_l = \frac{v_l}{M_l} \]

\(^1\)Caution! This classical limit is subject to controversy...
Born-Oppenheimer approximation: the nuclear trajectories

Therefore, taking the gradient,

$$-\nabla_J \frac{\partial S_k}{\partial t} = \frac{1}{2} \nabla_J \sum_i M_i^{-1} (\nabla_i S_k)^2 + \nabla_J E_k$$

and rearranging this equation using $\nabla_J S_k / M_J = \nu^k_J$, we obtain the (familiar) Newton equation:

$$M_J \frac{d}{dt} \nu^k_J = -\nabla_J E_k$$

In Summary:

**Adiabatic BO MD**

$$\hat{\mathcal{H}}_{el}(r; R) \Phi_k(r; R) = E^el_k(R) \Phi_k(r; R)$$

$$M_I \ddot{R}_I = -\nabla_I E^el_k(R) = -\nabla_I \langle \Phi_k | \hat{\mathcal{H}}_{el} | \Phi_k \rangle$$
Mean-field vs. BO MD (adiabatic case)

Ehrenfest dynamics

\[ i\hbar \frac{\partial \Phi(r; R, t)}{\partial t} = \hat{H}_{el}(r; R)\Phi(r; R, t) \]

\[ M_i \ddot{R}_i = -\nabla_I \langle \hat{H}_{el}(r; R) \rangle \]

Explicit time dependence of the electronic wavefunction.

Born-Oppenheimer dynamics

\[ \hat{H}_{el}(r; R)\Phi_k(r; R) = E_{el}^k(R)\Phi_k(r; R) \]

\[ M_i \ddot{R}_i = -\nabla_I E_{el}^k(R) = -\nabla_I \langle \Phi_k | \hat{H}_{el} | \Phi_k \rangle \]

The electronic wavefunction are static (only implicit time-dependence.)

## Exact quantum dynamics?

Can we derive “exact” quantum equations of motion for the nuclei? (without taking the classical limit $\hbar \to 0$?)
Tarjectory-based quantum and mixed QM-CL solutions

We can “derive” the following trajectory-based solutions:

- **Nonadiabatic Ehrenfest dynamics**

- **Adiabatic Born-Oppenheimer MD equations**

- **Nonadiabatic Bohmian Dynamics (NABDY)**
  - Nonadiabatic Trajectory Surface Hopping (TSH) dynamics

- **Time dependent potential energy surface approach**
  - based on the exact decomposition: \( \Psi(r, R, t) = \Omega(R, t)\Phi(r, t) \).
Nonadiabatic dynamics: Multi-trajectory solutions
Nonadiabatic Bohmian dynamics

Pioneers in quantum hydrodynamics: D. Bohm, P. R. Holland, R. E. Wyatt, and many others.
NABDY: “exact” trajectory-based nonadiabatic dynamics

Using

\[
\psi(r, R, t) = \sum_{j}^{\infty} \phi_j(r; R) \Omega_j(R, t)
\]

\[
\Omega_j(R, t) = A_j(R, t) \exp \left[ \frac{i}{\hbar} S_j(R, t) \right]
\]

in the exact time-dependent Schrödinger equation for the nuclear wavefunction we get

\[
-\frac{\partial S_j(R, t)}{\partial t} = \sum_{\gamma} \frac{1}{2M_\gamma} (\nabla_\gamma S_j(R, t))^2 + E^el_j(R) - \sum_{\gamma} \frac{\hbar^2}{2M_\gamma} \frac{\nabla_\gamma^2 A_j(R, t)}{A_j(R, t)}
\]

\[
+ \sum_{\gamma i} \frac{\hbar^2}{2M_\gamma} \frac{D^\gamma_{ji}(R) A_i(R, t)}{A_j(R, t)} \Re \left[ e^{i\phi} \right] - \sum_{\gamma, i \neq j} \frac{\hbar^2}{M_\gamma} \frac{d^\gamma_{ji}(R) \nabla_\gamma A_i(R, t)}{A_j(R, t)} \Im \left[ e^{i\phi} \right]
\]

\[
+ \sum_{\gamma, i \neq j} \frac{\hbar}{M_\gamma} \frac{d^\gamma_{ji}(R) A_i(R, t)}{A_j(R, t)} \nabla_\gamma S_i(R, t) \Im \left[ e^{i\phi} \right]
\]

and

\[
\frac{\partial A_j(R, t)}{\partial t} = - \sum_{\gamma} \frac{1}{M_\gamma} \nabla_\gamma A_j(R, t) \nabla_\gamma S_j(R, t) - \sum_{\gamma} \frac{1}{2M_\gamma} A_j(R, t) \nabla_\gamma^2 S_j(R, t)
\]

\[
+ \sum_{\gamma i} \frac{\hbar}{2M_\gamma} \frac{D^\gamma_{ji}(R) A_i(R, t)}{S_i(R, t)} \Re \left[ e^{i\phi} \right] - \sum_{\gamma, i \neq j} \frac{\hbar}{M_\gamma} \frac{d^\gamma_{ji}(R) \nabla_\gamma A_i(R, t)}{S_i(R, t)} \Re \left[ e^{i\phi} \right]
\]

\[
- \sum_{\gamma, i \neq j} \frac{1}{M_\gamma} d^\gamma_{ji}(R) A_i(R, t) \nabla_\gamma S_j(R, t) \Im \left[ e^{i\phi} \right]
\]

where both \( S_j(R, t) \) and \( A_j(R, t) \) are real fields and \( \phi = \frac{1}{\hbar} (S_i(R, t) - S_j(R, t)) \).
From the NABDY equations we can obtain a Newton-like equation of motion (using the HJ definition of the momenta $\nabla_\beta S_j(R, t) = P^j_\beta$)

$$M_\beta \frac{d^2 R_\beta}{(dt^j)^2} = -\nabla_\beta \left[ E^j_{el}(R) + Q_j(R, t) + \sum_i D_{ij}(R, t) \right]$$

where $Q_j(R, t)$ is the quantum potential responsible for all coherence/decoherence “intrasurface” QM effects, and $D_{ij}(R, t)$ is the nonadiabatic potential responsible for the amplitude transfer among the different PESs.

Tarjectory-based quantum and mixed QM-CL solutions

We can “derive” the following trajectory-based solutions:

- **Nonadiabatic Ehrenfest dynamics**

- **Adiabatic Born-Oppenheimer MD equations**

- **Nonadiabatic Bohmian Dynamics (NABDY)**

- **Nonadiabatic Trajectory Surface Hopping (TSH) dynamics**

- **Time dependent potential energy surface approach**
  - based on the exact decomposition: $\Psi(r, R, t) = \Omega(R, t)\Phi(r, t)$.
Applications in Photochemistry and Photophysics

Trajectory-based solutions of the “exact” nonadiabatic equations are still impractical.

Approximate solutions are available. Among the most popular is

Trajectory Surface Hopping (TSH)
The trajectory surface hopping dynamics (1)

TSH is a mixed quantum-classical theory

The classical component

- ensemble of classical trajectories following Newton’s equation of motion

  \[
  \frac{dP_j^\beta(t)}{dt^j} = -\nabla \beta E_j^\rho(R(t))
  \]

- trajectories are independent (ITA).
- No coherence
- density of trajectories \((^{\text{CL}}\rho_j(R(t), t))\) at each time step reproduces a ‘classical distribution’ on the different PESs.

\[
^{\text{CL}}\rho_k^{\alpha}(R^{\alpha}, t^{\alpha}) = \frac{N_k^{\alpha}(R^{\alpha}, dV, t^{\alpha})}{N_{\text{tot}}} \frac{1}{dV} \sim |\Omega_k(R^{\alpha}, t^{\alpha})|^2
\]
The trajectory surface hopping dynamics (2)

The quantum component

- To each trajectory there are quantum amplitudes $^{QM}C_j(R(t), t)$ associated to each PES:

  \[ \{ C_0(R(t), t), C_1(R(t), t), C_2(R(t), t), \ldots \} \].

- They evolve according to

  \[
i\hbar \frac{dC_j}{dt} = C_j E_j^e - i\hbar \sum_i \left( d_{ji} \cdot \dot{R}C_i \right)
\]

- $^{QM}C_j(R(t), t)$ determine the surface hopping probabilities,

  \[
  \rho_{i \rightarrow j}^{[\alpha]}(\Delta t) = -2 \int_t^{t+\Delta t} \Re \left[ C_i^{[\alpha]}(\tau) C_j^{[\alpha]}(\tau)^* \dot{R}(\tau) \cdot d_{ij}(R(\tau)) \right] d\tau
  \]

  so that: $^{QM}C_j^2(R(t), t) \equiv ^{CL}\rho_j(R(t), t)$. 

TDDFT in mixed quantum-classical dynamics
Tully’s surface hopping - Summary

Tully’s surface hopping

\[ i\hbar \dot{C}_k^\alpha(t) = \sum_j C_j^\alpha(t)(H_{kj} - i\hbar \dot{R}^\alpha \cdot d_{kj}^\alpha) \]

\[ M_l \ddot{R}_l = -\nabla_l E_{el}^l(R) \]

\[ \sum_{l \leq k-1} g_{jl}^\alpha < \zeta < \sum_{l \leq k} g_{jl}^\alpha , \]

Some warnings:

1. Evolution of classical trajectories (no QM effects – such as tunneling – are possible).
2. Rescaling of the nuclei velocities after a surface hop (to ensure energy conservation) is still a matter of debate.
3. Depending on the system studied, many trajectories could be needed to obtain a complete statistical description of the non-radiative channels.

For more details (and warnings) about Tully’s surface hopping, see G. Granucci and M. Persico, J Chem Phys 126, 134114 (2007).

CASSCF PESs for the radical cation ($Q_{14}$: symmetric stretch, $\theta$: torsional angle).
Mixed quantum-classical dynamics

Trajectory Surface Hopping

Comparison with wavepacket dynamics

Nuclear wavepacket dynamics on fitted potential energy surfaces (using MCTDH with 5 modes). Reappearing of the wavepacket in $S_1$ after $\sim 40$fs.

JPCA,107,621 (2003)
Comparison with wavepacket dynamics

On-the-fly dynamics with 80 trajectories (crosses).

Trajectories are not coming back close to the conical intersection.

What is the reason for this discrepancy? The independent trajectory approximation?, i.e. the fact that trajectories are not correlated? (Or it has to do with differences in the PESs?)

JPCA,107,621 (2003)

JPCA, 107, 621 (2003)
Tarjectory-based quantum and mixed QM-CL solutions

We can “derive” the following trajectory-based solutions:

- **Nonadiabatic Ehrenfest dynamics**

- **Adiabatic Born-Oppenheimer MD equations**

- **Nonadiabatic Bohmian Dynamics (NABDY)**

- **Nonadiabatic Trajectory Surface Hopping (TSH) dynamics**

- **Time dependent potential energy surface approach**
  based on the exact decomposition: \( \psi(r, R, t) = \Omega(R, t)\Phi(r, t) \).
Coupled-trajectories mixed quantum-classical (CT-MQC)

Why do we need another trajectory based approach?

Requirements:

- Existence of an exact limit - tuneable parameters
- Description of quantum coherence/decoherence effects
- Simple trajectory-based implementation
- Densityfunctionalization
- Parallelization

CT-MQC literature:

Derivation of the CT-MQC dynamics

The starting point is the \textit{exact factorization theorem}, which prescribes

\[
\Psi(r, R, t) = \chi(R, t)\Phi_R(r, t)
\]

as solution of the td-SE \(i\hbar\partial_t\Psi(r, R, t) = \hat{H}(r, R)\Psi(r, R, t)\).

The equations of motion (EOM) are

\[
\begin{align*}
    i\hbar\partial_t \Phi_R(r, t) &= \left(\hat{H}_{BO}(r, R) + \hat{U}^{\text{coup}}_{\text{en}}[\Phi_R, \chi] - \epsilon(R, t)\right) \Phi_R(r, t) \\
    i\hbar\partial_t \chi(R, t) &= \left(\sum_{\nu=1}^{N_n} \left(-i\hbar\nabla_{\nu} + A_{\nu}(R, t)\right)^2/2M_{\nu} + \epsilon(R, t)\right) \chi(R, t) \\
\end{align*}
\]

- \(\epsilon(R, t) = \langle \Phi_R(t)|\hat{H}_{BO} + \hat{U}^{\text{coup}}_{\text{en}} - i\hbar\partial_t|\Phi_R(t)\rangle_r\) is the td-PES.
- \(\hat{U}^{\text{coup}}_{\text{en}}[\Phi_R, \chi] = \sum_{\nu} \left((-i\hbar\nabla_{\nu} + A_{\nu})^2/2M_{\nu} + (-i\hbar\nabla_{\nu}\chi/\chi + A_{\nu})(-i\hbar\nabla_{\nu} + A_{\nu})/M_{\nu}\right)\)
- \(A_{\nu}(R, t) = \langle \Phi_R(t)| - i\hbar\nabla_{\nu}\Phi_R(t)\rangle_r\) is a td vector quantum potential.

Derivation of the CT-MQC dynamics

The starting point is the **exact factorization theorem**, which prescribes

\[
\Psi(r, R, t) = \chi(R, t)\Phi_R(r, t)
\]

as solution of the td-SE \( i\hbar \partial_t \Psi(r, R, t) = \hat{H}(r, R)\Psi(r, R, t) \).

The equations of motion (EOM) are

\[
i\hbar \partial_t \Phi_R(r, t) = \left( \hat{H}_{BO}(r, R) + \hat{U}_{en}^{coup}[\Phi_R, \chi] - \epsilon(R, t) \right) \Phi_R(r, t)
\]

\[
i\hbar \partial_t \chi(R, t) = \left( \sum_{\nu=1}^{N_n} \{-i\hbar \nabla_{\nu} + A_{\nu}(R, t)\}^2/2M_{\nu} + \epsilon(R, t) \right) \chi(R, t)
\]

- \( \epsilon(R, t) = \langle \Phi_R(t)|\hat{H}_{BO} + \hat{U}_{en}^{coup} - i\hbar \partial_t|\Phi_R(t)\rangle_r \) is the td-PES.
- \( \hat{U}_{en}^{coup}[\Phi_R, \chi] = \sum_{\nu} [(-i\hbar \nabla_{\nu} - A_{\nu})^2/2M_{\nu} + (-i\hbar \nabla_{\nu} \chi/\chi + A_{\nu})(-i\hbar \nabla_{\nu} + A_{\nu})/M_{\nu}] \)
- \( A_{\nu}(R, t) = \langle \Phi_R(t)| - i\hbar \nabla_{\nu} \Phi_R(t) \rangle_r \) is a td vector quantum potential.

Derivation of the CT-MQC dynamics

The starting point is the exact factorization theorem, which prescribes

$$\Psi(r, R, t) = \chi(R, t)\Phi_R(r, t)$$

as solution of the td-SE

$$i\hbar \partial_t \Psi(r, R, t) = \hat{H}(r, R)\Psi(r, R, t).$$

The equations of motion (EOM) are

$$i\hbar \partial_t \Phi_R(r, t) = \left( \hat{H}_{BO}(r, R) + \hat{U}_{\text{coup}}^{\text{en}}[\Phi_R, \chi] - \epsilon(R, t) \right) \Phi_R(r, t)$$

$$i\hbar \partial_t \chi(R, t) = \left( \sum_{\nu=1}^{N_n} \left\{-i\hbar \nabla_\nu + A_\nu(R, t) \right\}^2 / 2M_\nu + \epsilon(R, t) \right) \chi(R, t)$$

- $\epsilon(R, t) = \langle \Phi_R(t)|\hat{H}_{BO} + \hat{U}_{\text{coup}}^{\text{en}} - i\hbar \partial_t |\Phi_R(t)\rangle_r$ is the td-PES.
- $\hat{U}_{\text{coup}}^{\text{en}}[\Phi_R, \chi] = \sum_{\nu} \left\{(-i\hbar \nabla_\nu - A_\nu)^2 / 2M_\nu + (-i\hbar \nabla_\nu \chi / \chi + A_\nu)(-i\hbar \nabla_\nu + A_\nu) / M_\nu \right\}$
- $A_\nu(R, t) = \langle \Phi_R(t) | - i\hbar \nabla_\nu \Phi_R(t) \rangle_r$ is a td vector quantum potential.

Derivation of the CT-MQC dynamics

The starting point is the exact factorization theorem, which prescribes

\[ \psi(r, R, t) = \chi(R, t) \phi_R(r, t) \]

as solution of the td-SE

\[ i\hbar \partial_t \psi(r, R, t) = \hat{H}(r, R) \psi(r, R, t). \]

The equations of motion (EOM) are

\[
\begin{align*}
    i\hbar \partial_t \phi_R(r, t) &= \left( \hat{H}_{BO}(r, R) + \hat{U}^{\text{coup}}_{en}[\phi_R, \chi] - \epsilon(R, t) \right) \phi_R(r, t) \\
    i\hbar \partial_t \chi(R, t) &= \left( \sum_{\nu=1}^{N_n} \left\{-i\hbar \nabla_{\nu} + A_{\nu}(R, t)\right\}^2/2M_{\nu} + \epsilon(R, t) \right) \chi(R, t)
\end{align*}
\]

- \( \epsilon(R, t) = \langle \phi_R(t) | \hat{H}_{BO} + \hat{U}^{\text{coup}}_{en} - i\hbar \partial_t | \phi_R(t) \rangle_r \) is the td-PES.

- \( \hat{U}^{\text{coup}}_{en}[\phi_R, \chi] = \sum_{\nu} \left\{-i\hbar \nabla_{\nu} - A_{\nu}\right\}^2/2M_{\nu} + \left\{-i\hbar \nabla_{\nu} \chi/\chi + A_{\nu}\right\}\left(-i\hbar \nabla_{\nu} + A_{\nu}\right)/M_{\nu} \]

- \( A_{\nu}(R, t) = \langle \phi_R(t) | -i\hbar \nabla_{\nu} \phi_R(t) \rangle_r \) is a td vector quantum potential.

Derivation of the CT-MQC dynamics

The starting point is the **exact factorization theorem**, which prescribes

\[ \Psi(r, R, t) = \chi(R, t) \Phi_R(r, t) \]

as solution of the td-SE

\[ i\hbar \partial_t \Psi(r, R, t) = \hat{H}(r, R) \Psi(r, R, t). \]

The equations of motion (EOM) are

\[ i\hbar \partial_t \Phi_R(r, t) = \left( \hat{H}_{BO}(r, R) + \hat{U}_{en}^{coup}[\Phi_R, \chi] - \epsilon(R, t) \right) \Phi_R(r, t) \]

\[ i\hbar \partial_t \chi(R, t) = \left( \sum_{\nu=1}^{N_n} \left\{ -i\hbar \nabla_\nu + A_\nu(R, t) \right\}^2 / 2M_\nu + \epsilon(R, t) \right) \chi(R, t) \]

- \( \epsilon(R, t) = \langle \Phi_R(t) | \hat{H}_{BO} + \hat{U}_{en}^{coup} - i\hbar \partial_t | \Phi_R(t) \rangle \) \( _{r} \) is the td-PES.
- \( \hat{U}_{en}^{coup}[\Phi_R, \chi] = \sum_{\nu} \left[ \left( -i\hbar \nabla_\nu - A_\nu \right)^2 / 2M_\nu + \left( -i\hbar \nabla_\nu \chi / \chi + A_\nu \right)(-i\hbar \nabla_\nu + A_\nu) / M_\nu \right] \)
- \( A_\nu(R, t) = \langle \Phi_R(t) | -i\hbar \nabla_\nu \Phi_R(t) \rangle \) \( _{r} \) is a td vector quantum potential.

Implementation of the CT-MQC dynamics

Mixed quantum-classical limit

(i) Newton EOM with forces from the td vector $A_\nu(R, t)$ and scalar td $\epsilon(R, t)$ potentials

(ii) Born-Huang representation for the electronic wavefunction

$$\Phi_R(r, t) = \sum_l C_l(R, t) \phi_R^{(l)}(r)$$

(iii) Classical limit for the vector quantum potential (part of $\hat{U}_{en}^{coup}[\Phi_R, \chi]$: $-i\hbar\nabla_\nu \chi(R)/\chi(R)$

(iv) Swarm of (correlated) trajectories to compute properties of the nu-wavefunction, $\chi(R)$.

$\to$ Gaussian wavepackets moving with the trajectories.

The electronic and nuclear equations in the MQC-limit of the EXF are

State populations: $\dot{C}_l^{(\alpha)}(t) = \dot{C}_{Eh. l}^{(\alpha)}(t) + \dot{C}_{qm l}^{(\alpha)}(t)$

Nuclear forces: $F_\nu^{(\alpha)}(t) = F_{Eh. \nu}^{(\alpha)}(t) + F_{qm \nu}^{(\alpha)}(t)$

The Ehrenfest-like terms

\[
\dot{C}_{\text{Eh.},l}^{(\alpha)}(t) = \frac{-i}{\hbar} \varepsilon_{BO}^{(l)(\alpha)} C_{l}^{(\alpha)}(t) - \sum_{k} C_{k}^{(\alpha)}(t) \sum_{\nu=1}^{N_{n}} \frac{P_{\nu}^{(\alpha)}(t)}{M_{\nu}} \cdot d_{\nu,lk}^{(\alpha)} \\
F_{\text{Eh.},\nu}^{(\alpha)}(t) = -\sum_{k} |C_{k}^{(\alpha)}(t)|^{2} \nabla_{\nu} \varepsilon_{BO}^{(k)(\alpha)} - \sum_{k,l} C_{l}^{(\alpha)*}(t) C_{k}^{(\alpha)}(t) \left( \varepsilon_{BO}^{(k)(\alpha)} - \varepsilon_{BO}^{(l)(\alpha)} \right) d_{\nu,lk}^{(\alpha)},
\]

\(\varepsilon_{BO}^{(l)(\alpha)}\)  
adiabatic PES \(l\) evaluated at \(\alpha\)-th trajectory,

\(d_{\nu,lk}^{(\alpha)}\)  
NACV (\(\langle \varphi^{(l)(\alpha)}|\nabla_{\nu}\varphi^{(k)(\alpha)}\rangle_{r}\)) for trajectory \(\alpha\),

\(P_{\nu}^{(\alpha)}(t)\)  
classical momentum along the \(\alpha\)-th trajectory.

\(l, k\) is the state indices, \(\alpha\) the trajectory index, and \(\nu\) is the index over the nuclei.

Implementation of the CT-MQC dynamics

Quantum momentum terms (from exact factorization)

\[
\dot{C}_{qm\alpha}^l(t) = - \sum_{\nu=1}^{N_n} \frac{P_{\nu}^{(\alpha)}(t)}{\hbar M_\nu} \cdot \left[ \sum_k \left| C_k^{(\alpha)}(t) \right|^2 f_{k,\nu}^{(\alpha)}(t) - f_{l,\nu}^{(\alpha)}(t) \right] C_l^{(\alpha)}(t),
\]

\[
F_{qm\nu}^{(\alpha)}(t) = - \sum_l \left| C_l^{(\alpha)}(t) \right|^2 \left( \sum_{\nu'=1}^{N_n} \frac{2}{\hbar M_{\nu'}} P_{\nu'}^{(\alpha)}(t) \cdot f_{l,\nu'}^{(\alpha)}(t) \right) \left[ \sum_k \left| C_k^{(\alpha)}(t) \right|^2 f_{k,\nu}^{(\alpha)}(t) - f_{l,\nu}^{(\alpha)}(t) \right]
\]

\[
f_{k,\nu}^{(\alpha)}(t) \quad \text{integrated forces} = - \int^t dt' \nabla_{\nu \in BO}^{(k), (\alpha)}
\]

\[
P_{\nu}^{(\alpha)}(t) \quad \text{quantum momentum} = - \frac{\hbar}{2} \frac{\nabla_{\nu} \chi^{(\alpha)}(t)}{|\chi^{(\alpha)}(t)|^2}
\]

It induces coupling between the trajectories (beyond the ind. traj. appr. (ITA)).

\[l, k \text{ are state indices, } \alpha \text{ the trajectory index, and } \nu \text{ the index over the nuclei.}\]

CT-MQC dynamics: time-dependent potential energy lines
CT-MQC dynamics: time-dependent potential energy lines
Further extensions: nuclear quantum (tunneling) effects in CT-MQC

The quantum potential

$$Q(R, t) = - \sum_{\nu} \frac{\hbar}{2M_\nu} \frac{\nabla^2_\nu |\chi(R, t)|}{|\chi(R, t)|}$$

can be derived computed suing the Gaussian associated to the trajectories

$$|\chi(R, t)|^2 = \frac{1}{N_{tr}} \sum_{I=1}^{N_{tr}} \prod_{\nu=1}^{N_{nu}} G_{\sigma_{I,\nu}}(R_\nu; R^{(I)}_\nu(t))$$

where $G_{\sigma_{I,\nu}}(R_\nu; R^{(I)}_\nu(t))$ are normalized Gaussians centred at the classical trajectory $R^{(I)}(t)$ with variance $\sigma_{I,\nu}$,

$$\sigma_{I,\nu} = \sqrt{\overline{D}^2_{I,\nu} - \overline{D}_{I,\nu}^2} \quad \overline{D}_{I,\nu} = \frac{1}{n^{(I)}_{tr}} \sum_{J} |R^{(I)}_\nu - R^{(J)}_\nu|, \quad \overline{D}^2_{I,\nu} = \frac{1}{n^{(I)}_{tr}} \sum_{J} |R^{(I)}_\nu - R^{(J)}_\nu|^2$$

Further extensions: nuclear quantum (tunneling) effects in CT-MQC

Green: CT-MQC with no quantum potential.
Red: CT-MQC with quantum potential.
