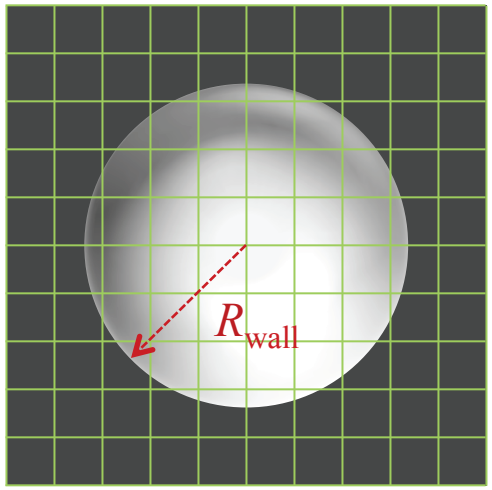
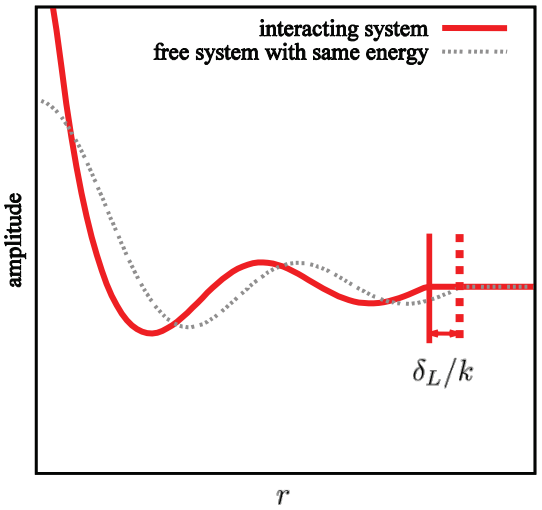
Spherical wall method

Borasoy, Epelbaum, Krebs, D.L., Meißner, EPJA 34 (2007) 185

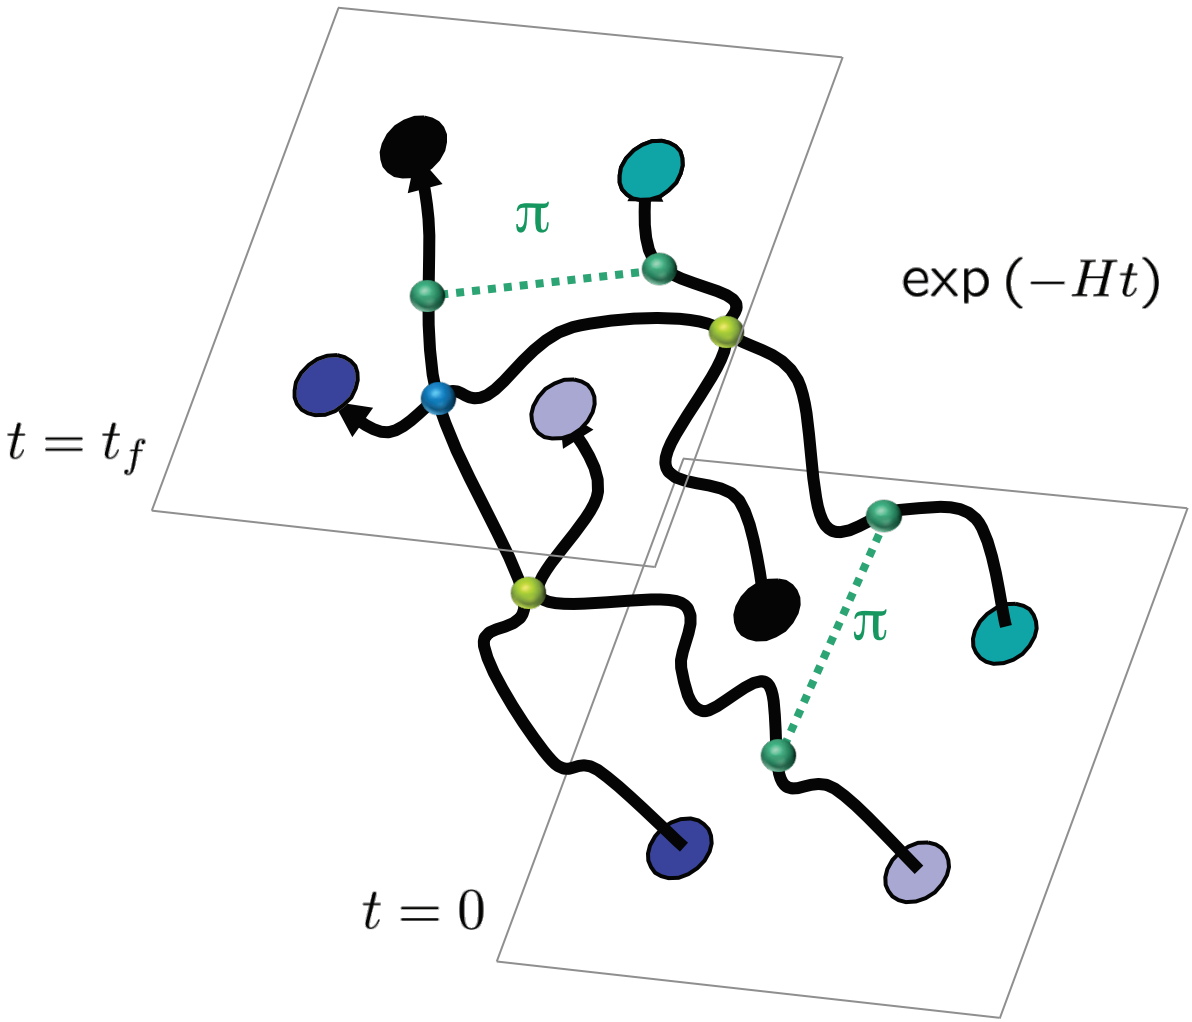
Spherical wall imposed in the center of mass frame



Representation	J_z	Example
A_1	$0 \bmod 4$	$Y_{0,0}$
T_1	$0, 1, 3 \bmod 4$	$\{Y_{1,0}, Y_{1,1}, Y_{1,-1}\}$
E	$0, 2 \bmod 4$	$\left\{Y_{2,0}, \frac{Y_{2,-2}+Y_{2,2}}{\sqrt{2}}\right\}$
T_2	$1, 2, 3 \bmod 4$	$\left\{Y_{2,1}, \frac{Y_{2,-2}-Y_{2,2}}{\sqrt{2}}, Y_{2,-1}\right\}$
A_2	$2 \bmod 4$	$\frac{Y_{3,2}-Y_{3,-2}}{\sqrt{2}}$



Euclidean time projection



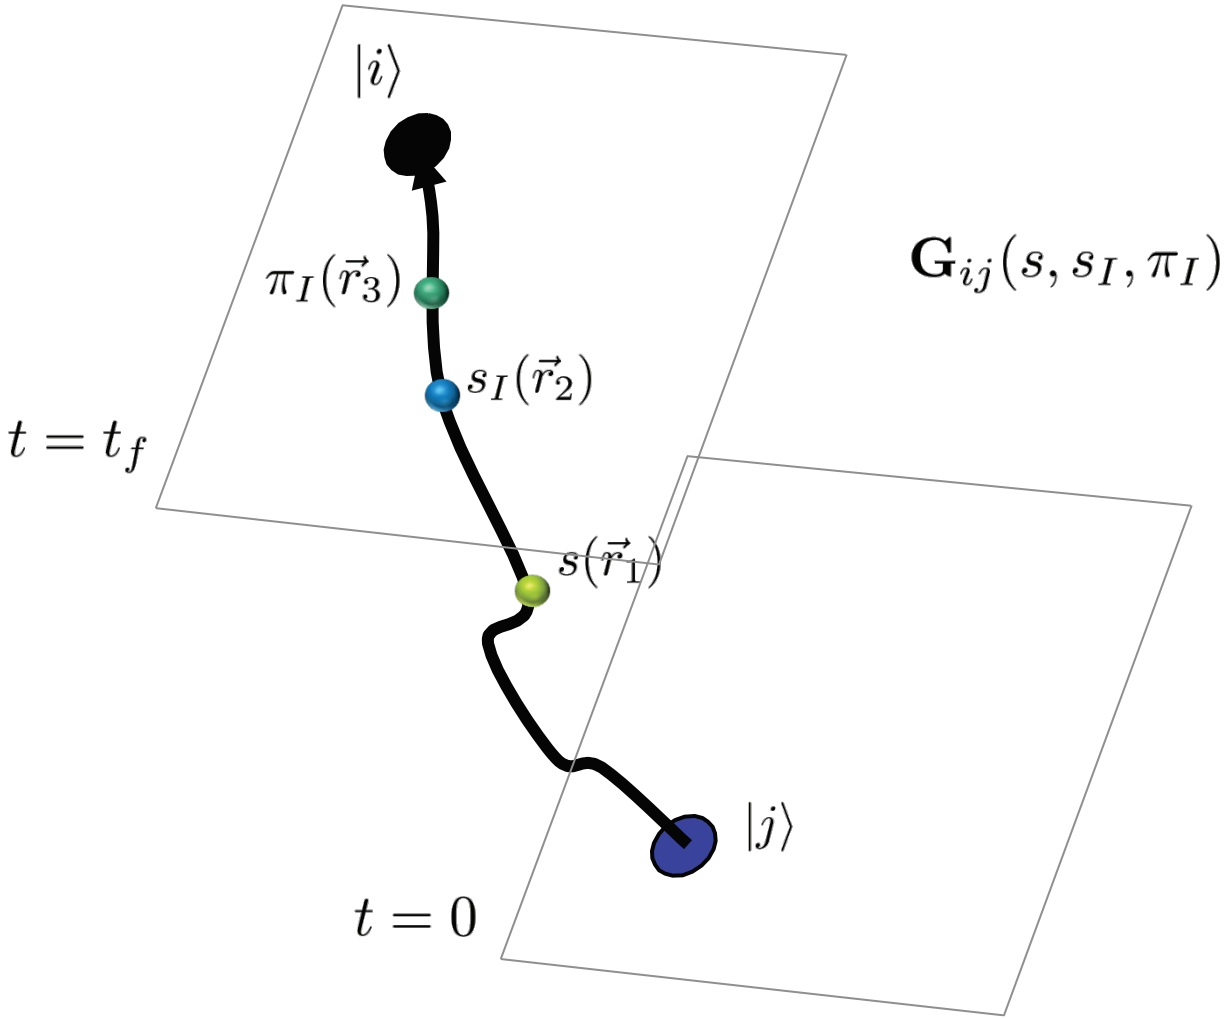
Auxiliary field method

We can write exponentials of the interaction using a Gaussian integral identity

$$\exp\left[-\frac{C}{2}(N^\dagger N)^2\right] \qquad \times \quad (N^\dagger N)^2$$

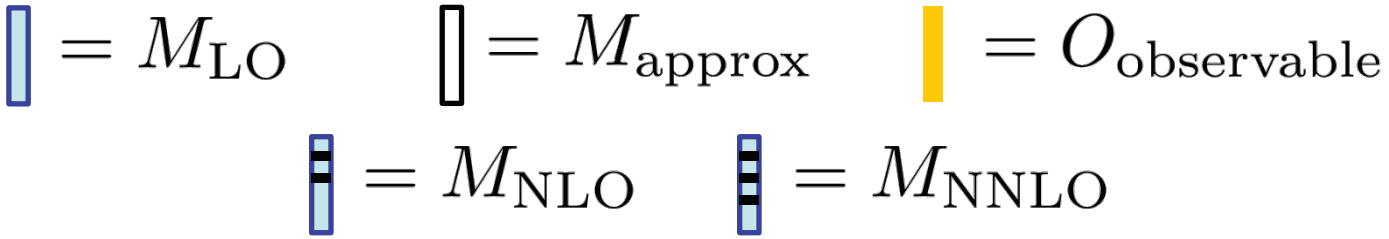
$$= \sqrt{\frac{1}{2\pi}} \int_{-\infty}^{\infty} ds \exp\left[-\frac{1}{2}s^2 + \sqrt{-C}\, s(N^\dagger N)\right] \qquad \rangle \bullet \; sN^\dagger N$$

We remove the interaction between nucleons and replace it with the interactions of each nucleon with a background field.

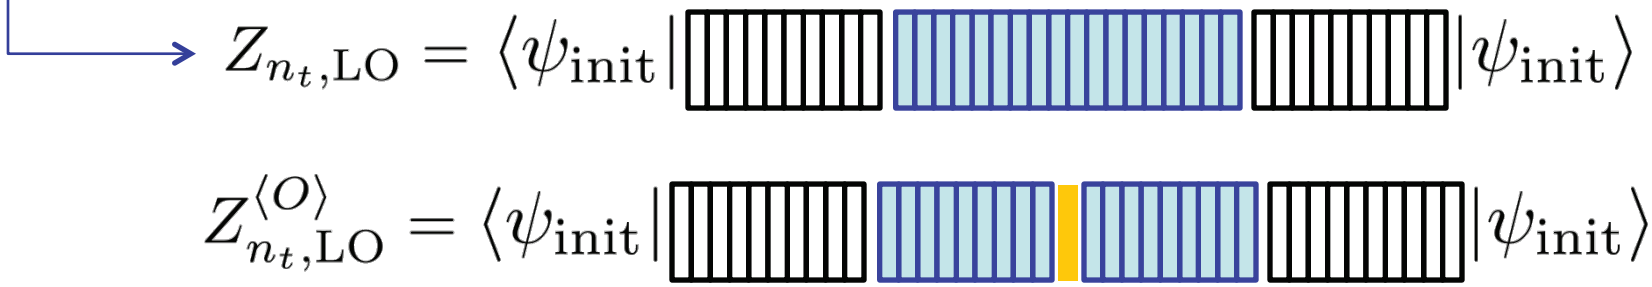


$|i\rangle$
$\pi_I(\vec{r}_3)$
$s_I(\vec{r}_2)$
$t = t_f$
$s(\vec{r}_1)$
$|j\rangle$
$t = 0$
$\mathbf{G}_{ij}(s, s_I, \pi_I)$

Schematic of lattice Monte Carlo calculation



Hybrid Monte Carlo sampling



$$e^{-E_{0,\mathrm{LO}} a_t} = \lim_{n_t \to \infty} Z_{n_t+1,\mathrm{LO}} / Z_{n_t,\mathrm{LO}}$$

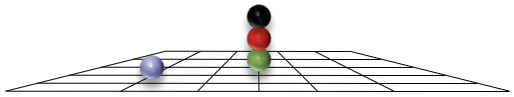
$$\langle O \rangle_{0,\mathrm{LO}} = \lim_{n_t \to \infty} Z^{\langle O \rangle}_{n_t,\mathrm{LO}} / Z_{n_t,\mathrm{LO}}$$

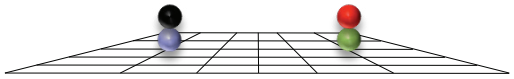
$$Z_{n_t,\mathrm{NLO}} = \langle \psi_{\mathrm{init}} |$$  $$| \psi_{\mathrm{init}} \rangle$$

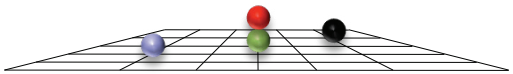
$$Z^{\langle O \rangle}_{n_t,\mathrm{NLO}} = \langle \psi_{\mathrm{init}} |$$  $$| \psi_{\mathrm{init}} \rangle$$

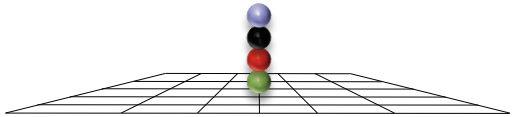
$$\langle O \rangle_{0,\mathrm{NLO}} = \lim_{n_t \to \infty} Z^{\langle O \rangle}_{n_t,\mathrm{NLO}} / Z_{n_t,\mathrm{NLO}}$$

Particle clustering included automatically

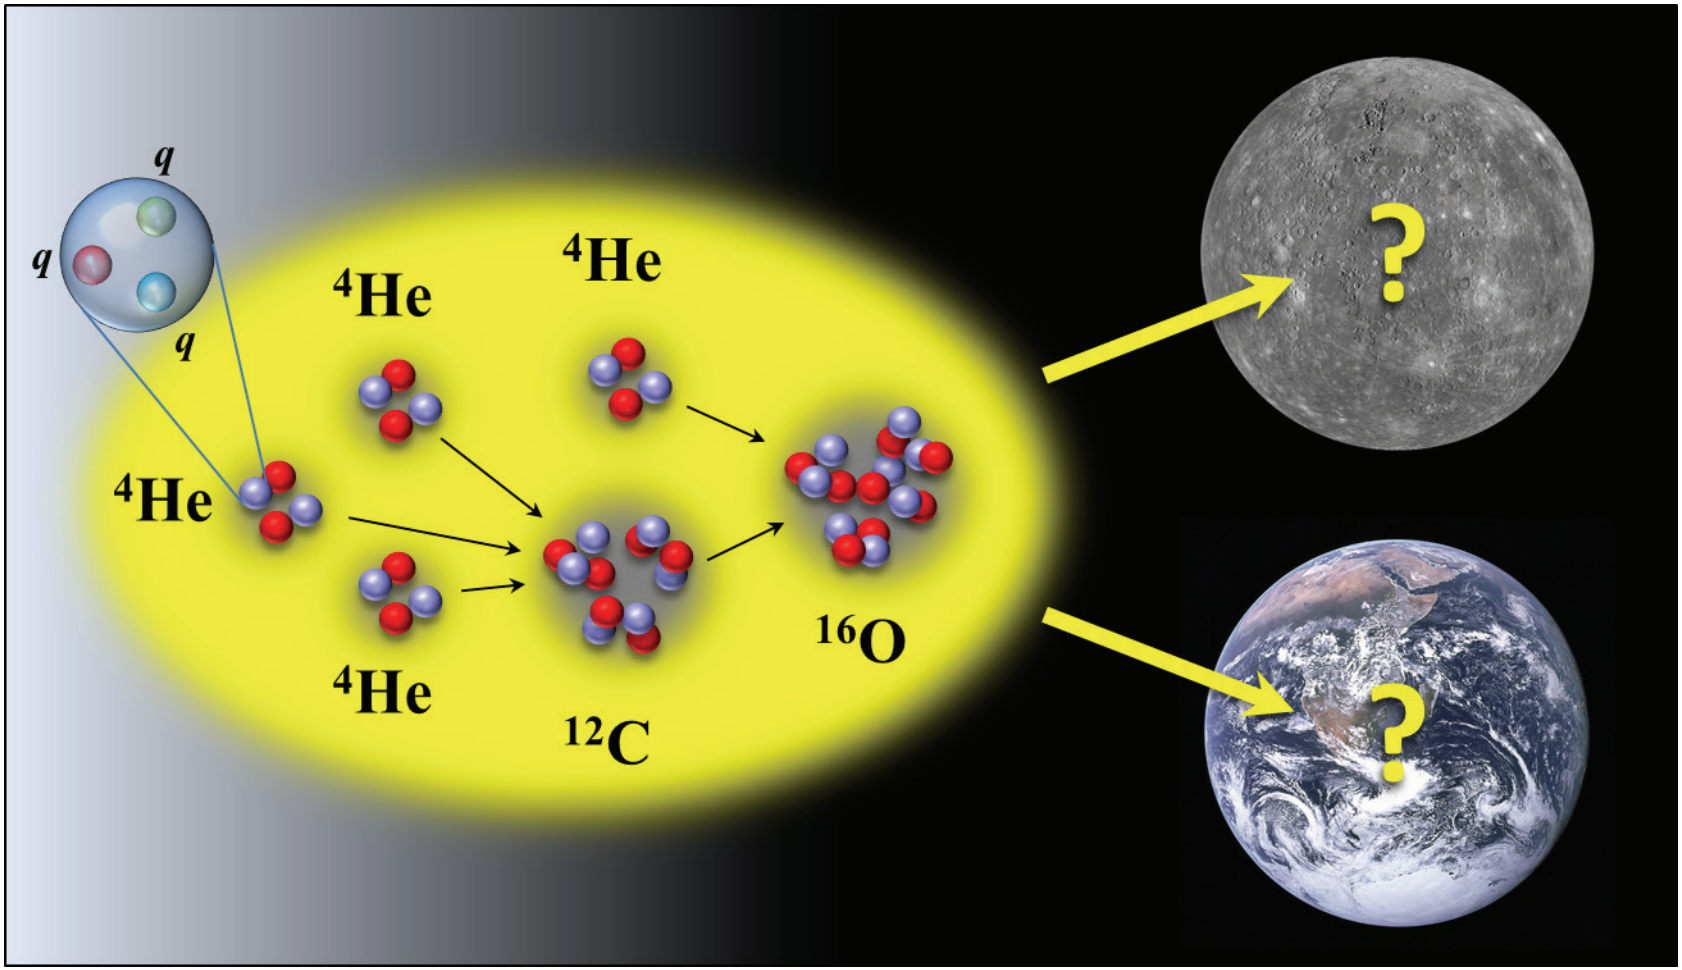




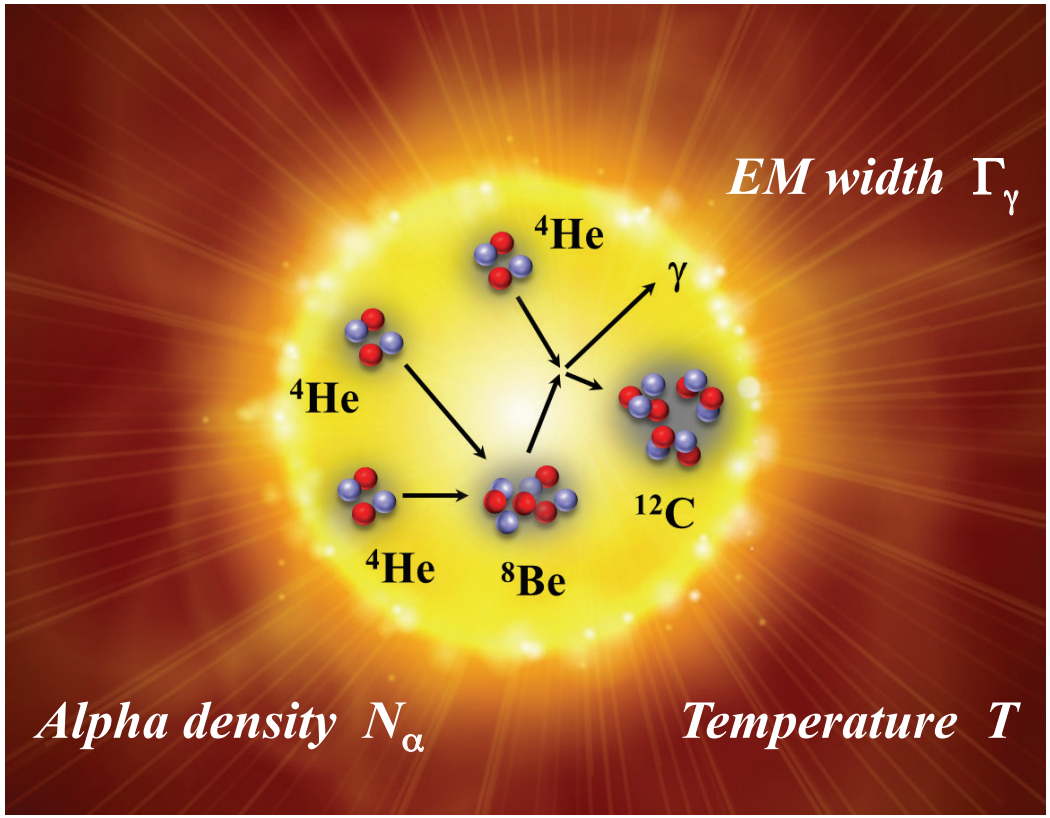




Light quark mass dependence of helium burning



Triple alpha reaction rate



$$r_{3\alpha} \propto \Gamma_\gamma \left(N_\alpha / k_B T\right)^3 \times \exp(-\varepsilon / k_B T)$$

$\varepsilon = E_h - 3E_\alpha$ Hoyle relative to triple-alpha

Is nature fine-tuned?

$$\varepsilon = E_h - 3E_\alpha \approx 400\,\mathrm{keV}$$

$\varepsilon > 500\,\mathrm{keV}$

Less resonance enhancement. Rate of carbon production smaller by several orders of magnitude. Low carbon abundance is unfavorable for carbon-based life.

$\varepsilon < 300\,\mathrm{keV}$

Carbon production occurs at lower stellar temperatures and oxygen production greatly reduced. Low oxygen abundance is unfavorable for carbon-based life.

Schlattl et al., Astrophys. Space Sci., 291, 27–56 (2004)

We investigate the dependence on the fundamental parameters of the standard model such as the light quark masses. Can be parameterized by the pion mass.

We find that the overbinding is eliminated with a
better NLO lattice action that fits the nuclear phase shifts
to higher momenta (work in progress)

Epelbaum, Krebs, Lähde, D.L, Meißner, Rupak, PRL112, 102501 (2014)

Sign oscillations

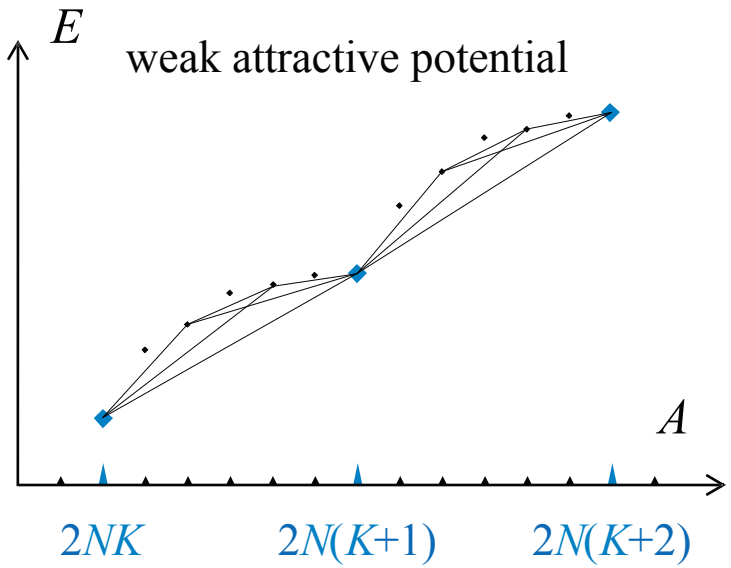
$$1 = (2-1)^{1000}$$
$$= 2^{1000} - 1000 \cdot 2^{999} + \frac{1000 \cdot 999}{2} \cdot 2^{998} - \cdots$$

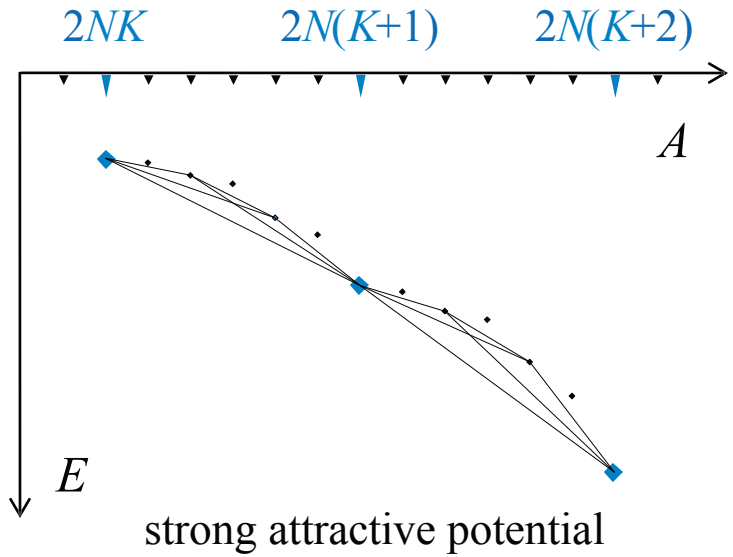
There are different types of sign oscillation problems. In explicit fermion simulations such as diffusion or Green's function Monte Carlo, the sign problem is due to Fermi statistics. In implicit fermion simulations such as auxiliary-field Monte Carlo, the sign problem is predominantly due to repulsive interactions.

Theorem: Any fermionic theory with SU(2*N*) symmetry and two-body potential with negative semi-definite Fourier transform obeys SU(2*N*) convexity bounds.

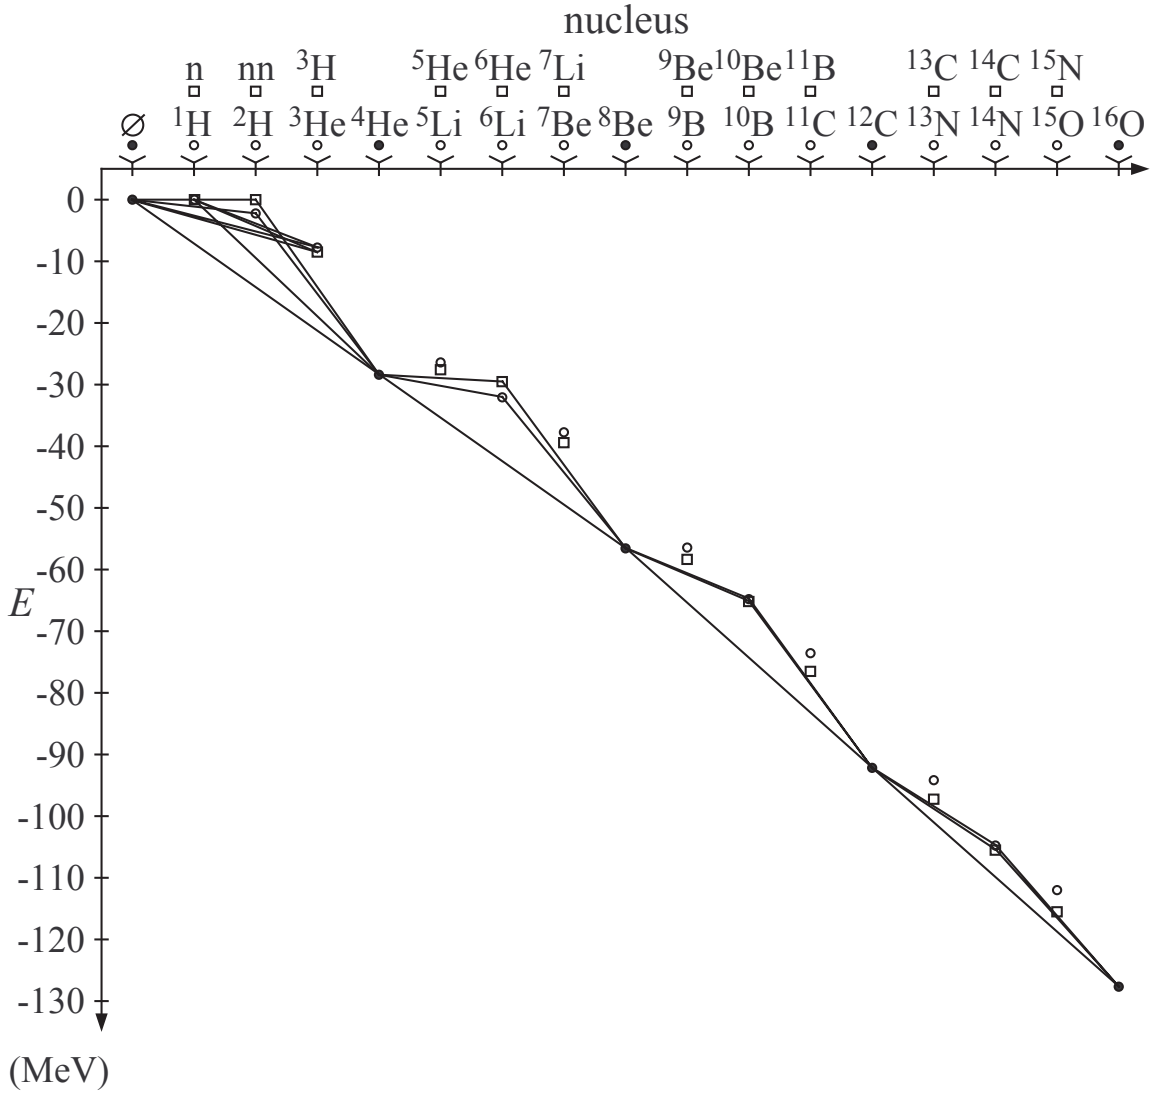
Corollary: System can be simulated without sign oscillations

Chen, D.L. Schäfer, PRL 93 (2004) 242302;
D.L., PRL 98 (2007) 182501





SU(4) convexity bounds



Symmetry Sign Extrapolation

Start with a physical Hamiltonian of interest that has a sign oscillation problem

$$H_{\mathrm{phys}}$$

Suppose there exists some SU(2*N*)-invariant Hamiltonian that can be tuned to reproduce the overall size, binding, and other relevant observables for the system of interest

$$H_{\mathrm{SU}(2N)}$$

Construct a one-parameter family interpolating between the two Hamiltonians

$$H_d = (1-d)\cdot H_{\mathrm{SU}(2N)} + d\cdot H_{\mathrm{phys}}$$

Simulations of neutron-rich matter

Pure neutron matter can be simulated using a trick which modifies the proton interactions to greatly reduce the sign problem. The modified proton interactions are allowed since there are no protons. Call this the pure neutron action.

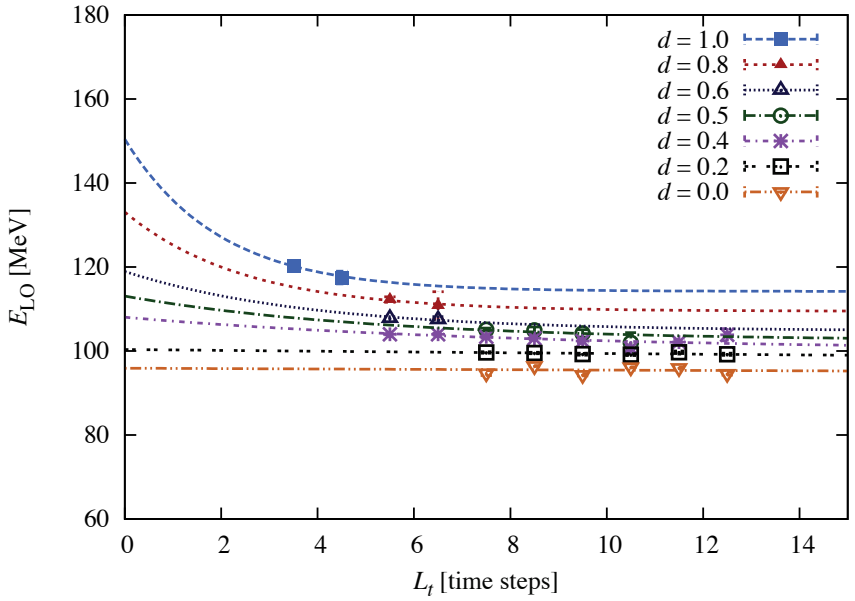
This trick is not available for neutron-rich matter with nonzero proton fraction. But we can use pure neutron matter as a benchmark test of our sign extrapolation method.

We simulate 12 neutrons in a $(7.9\ \mathrm{fm})^3$ periodic box using the symmetry sign extrapolation method and compare with pure neutron action results. Density is about $1/7^{\mathrm{th}}$ of nuclear matter density.

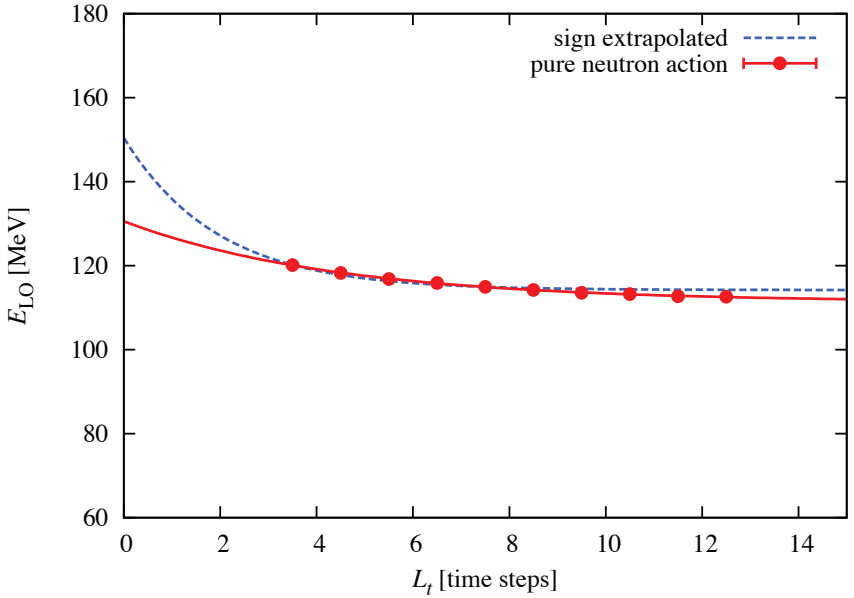
12 neutrons in $(7.9\ \mathrm{fm})^3$ periodic box

E_{LO}

sign extrapolation



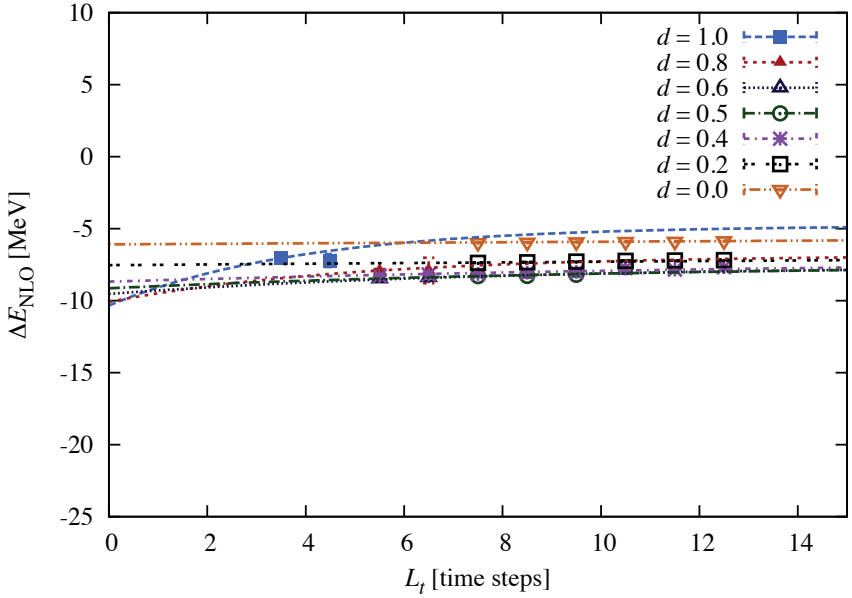
benchmark comparison



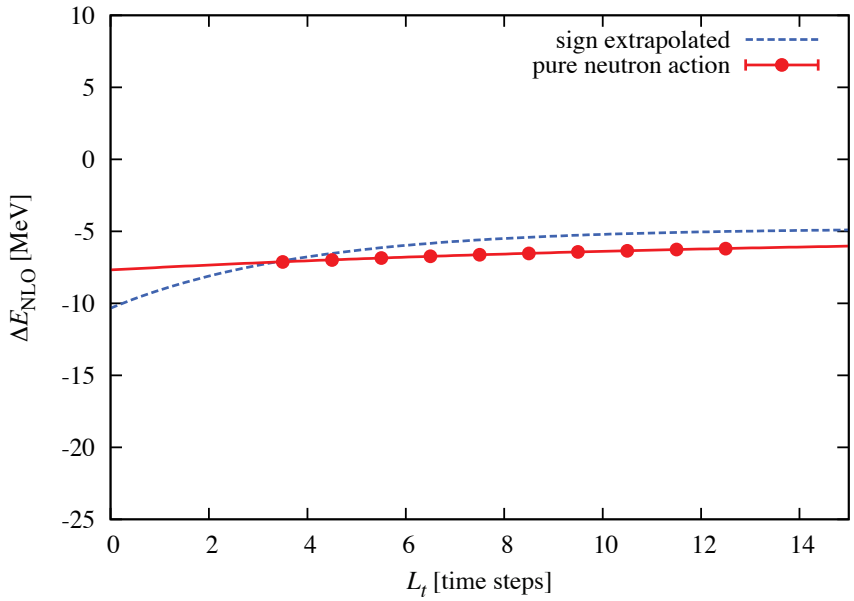
$a = 1.97\ \mathrm{fm}$

ΔE_{NLO}

sign extrapolation

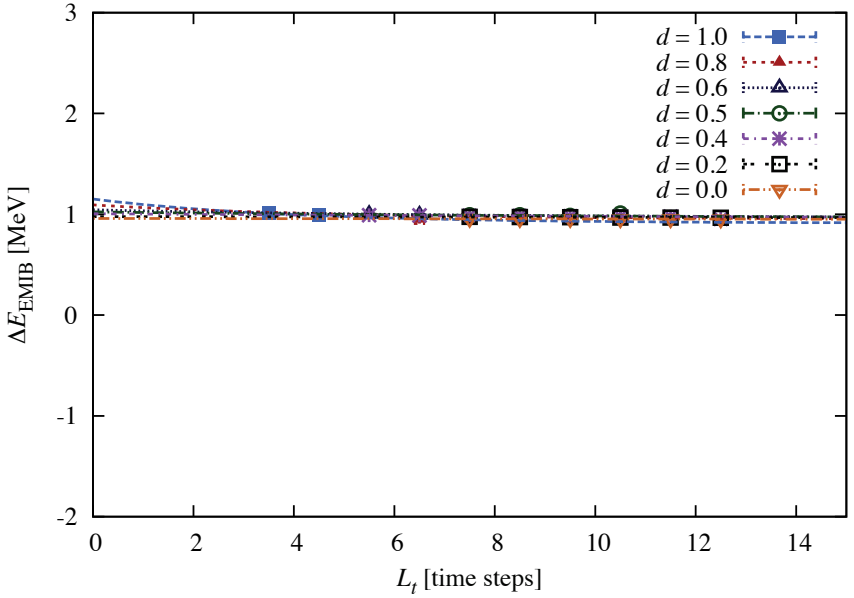


benchmark comparison

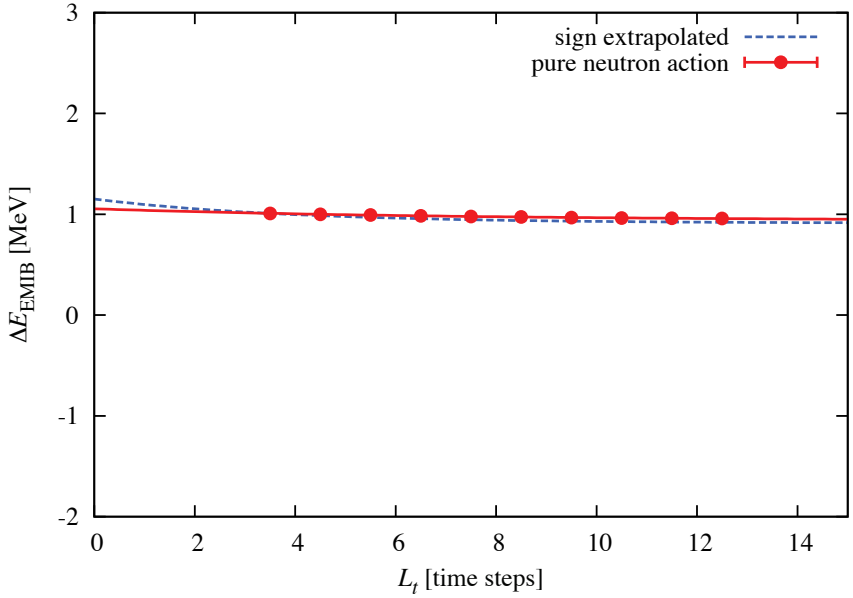


ΔE_{EMIB}

sign extrapolation

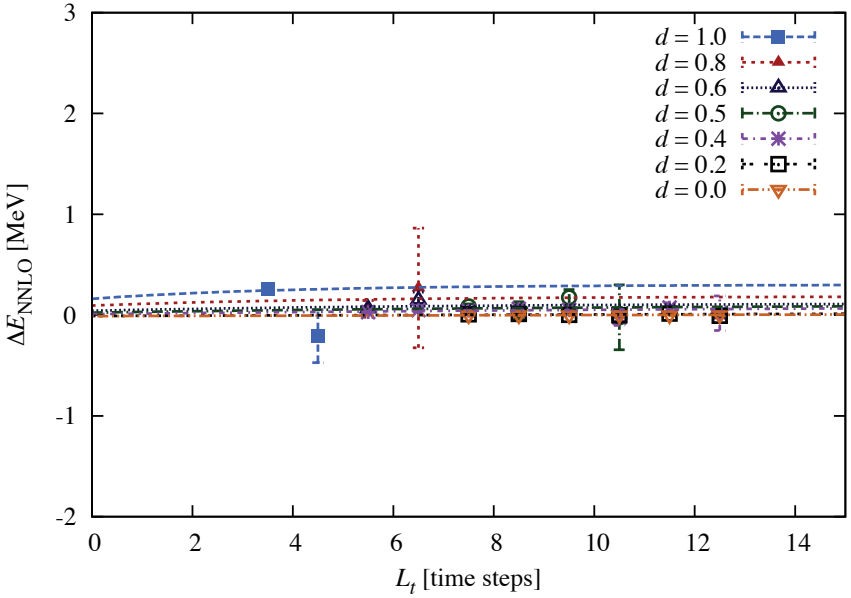


benchmark comparison

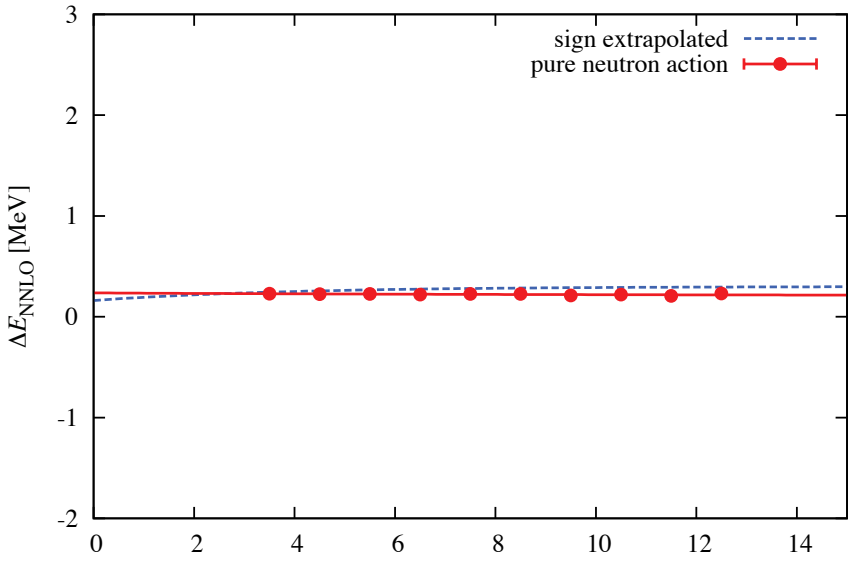


ΔE_{NNLO}

sign extrapolation



benchmark comparison



12 neutrons in $(7.9\ \mathrm{fm})^3$ periodic box

	E_{LO} [MeV]	ΔE_{NLO} [MeV]	ΔE_{EMIB} [MeV]	ΔE_{NNLO} [MeV]
Sign extrapolation	114(6)	-4.8(5)	0.911(18)	0.30(15)
Pure neutron benchmark	111.4(2)	-5.24(8)	0.936(2)	0.21(8)

with the method tested, we now add protons…

Work in progress

10 neutrons and 2 protons in $(7.9\ \mathrm{fm})^3$ periodic box

	E_{LO} [MeV]	ΔE_{NLO} [MeV]	ΔE_{EMIB} [MeV]	ΔE_{NNLO} [MeV]
Sign extrapolation	21.7(2.6)	2.15(19)	1.33(3)	-6.0(2)

$$E_{\mathrm{NNLO}} = 19(3)\,\mathrm{MeV}$$

Work in progress

How are the neutrons and protons arranged?

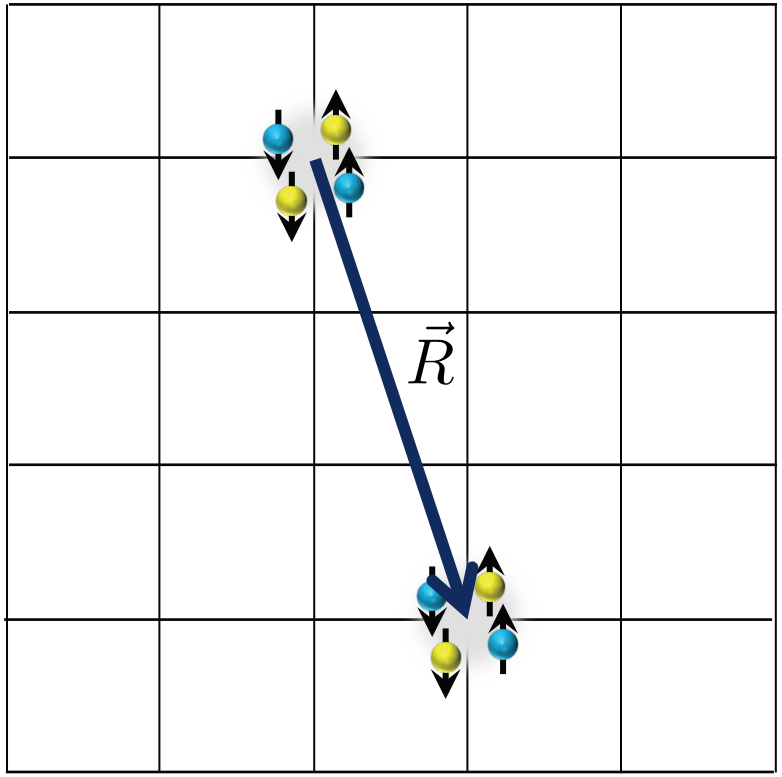
Adiabatic projection method

See Gautam's talk for more details



Use cluster wavefunctions for initial continuum scattering states

$|\vec{R}\rangle$

Use projection Monte Carlo to propagate cluster wavefunctions in Euclidean time

$$|\vec{R}\rangle_t = e^{-Ht}|\vec{R}\rangle$$

$|\vec{R}\rangle_t =$  $|\vec{R}\rangle$

Construct a norm matrix and matrix of expectation values

$\langle N\rangle_t = {}_t\langle\vec{R}'|\vec{R}\rangle_t =$

$\langle\vec{R}'|$  $|\vec{R}\rangle$

$\langle O\rangle_t = {}_t\langle\vec{R}'|O|\vec{R}\rangle_t =$

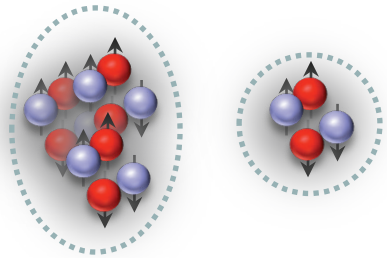
$\langle\vec{R}'|$  $|\vec{R}\rangle$

Compute the projected adiabatic matrix

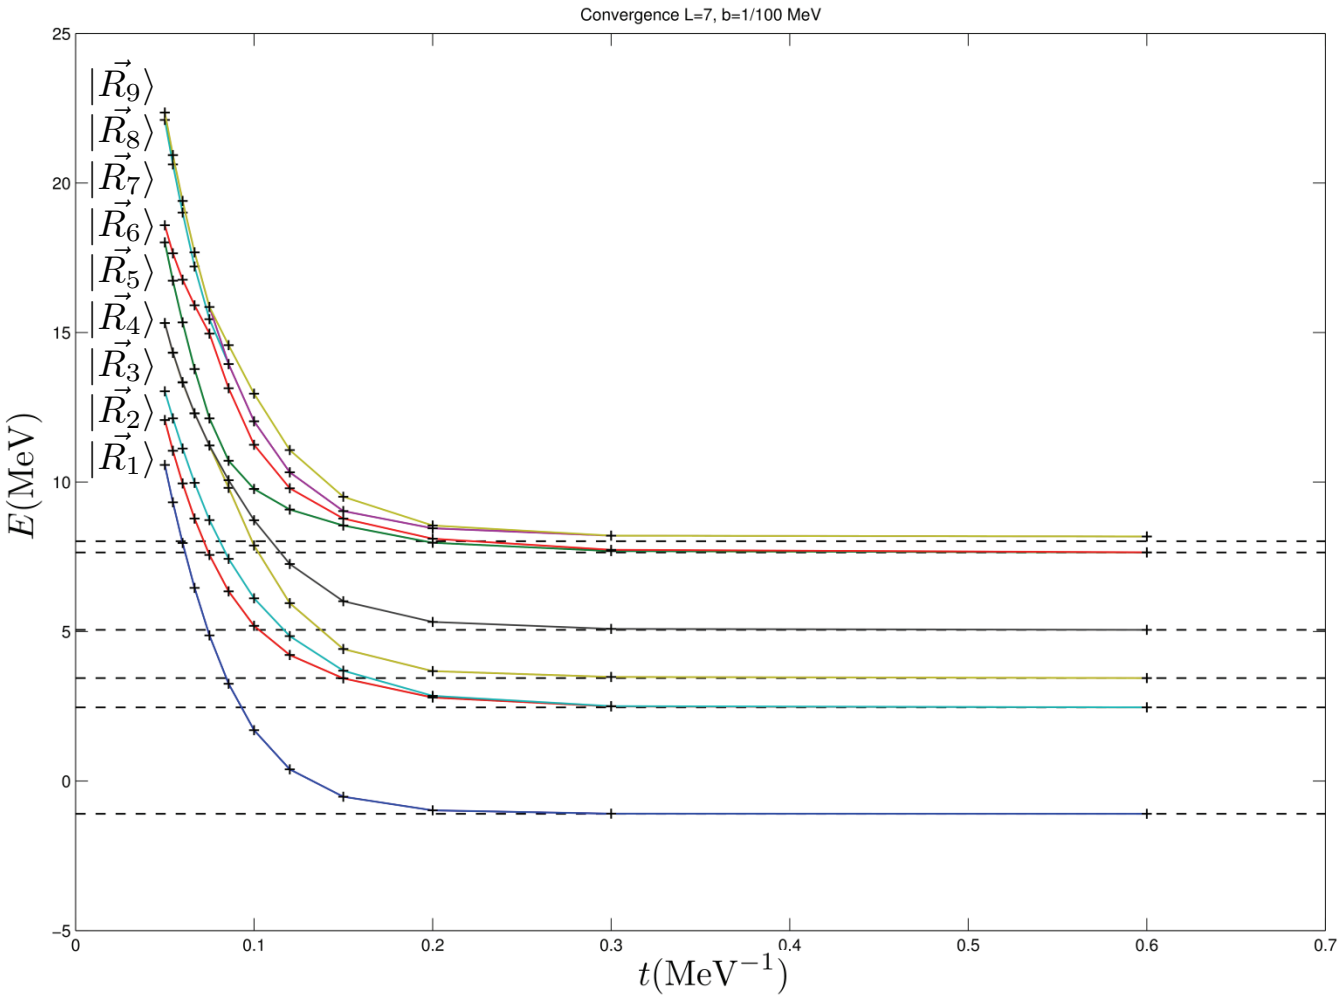
$$\langle O \rangle_{\rm adiab} = \langle N \rangle_t^{-1/2} \langle O \rangle_t \langle N \rangle_t^{-1/2}$$

Projected adiabatic Hamiltonian is now an effective two-body Hamiltonian. Similar in spirit to no-core shell model with resonating group method.

But some differences. Distortion of the nucleus wavefunctions is automatic due to projection in Euclidean time.

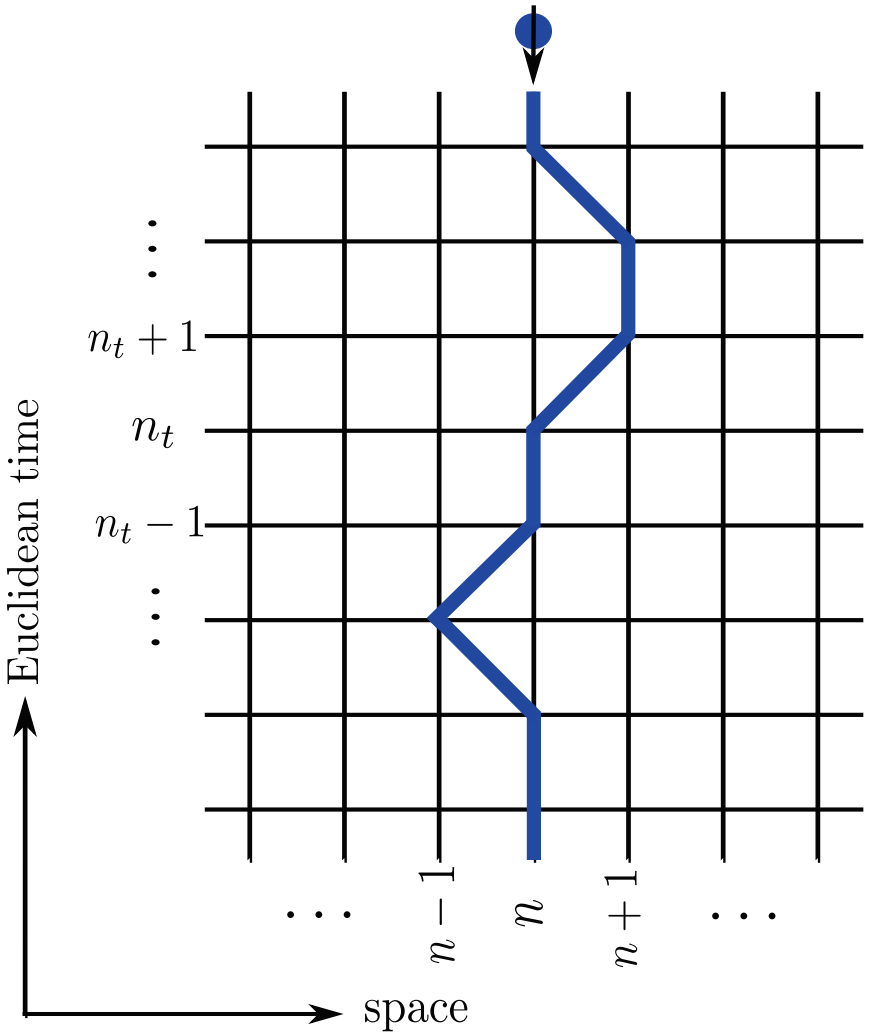


Example: Spin-quartet neutron-deuteron scattering



Pine, D.L., Rupak, EPJA 49 (2013) 151

Example: Adiabatic projection using Monte Carlo



Impurity lattice Monte Carlo

$$\langle \chi^{\downarrow}_{n_t+1} | \hat{M} | \chi^{\downarrow}_{n_t} \rangle = \left(\tfrac{\alpha_t}{2m}\right) : e^{-\alpha_t \hat{H}_0^{\uparrow}} :$$

$$\langle \chi^{\downarrow}_{n_t} | \hat{M} | \chi^{\downarrow}_{n_t-1} \rangle = \left(1 - \tfrac{3\alpha_t}{m}\right) : e^{-\alpha_t \hat{H}_0^{\uparrow} - \frac{\alpha_t C_0}{1-3\alpha_t/m} \rho_{\uparrow}(n)} :$$

Summary

A golden age for nuclear theory from first principles. Big science discoveries being made and many more around the corner.

Lattice effective field theory is a relatively new and promising tool that combines the framework of effective field theory and computational lattice methods.

Additional topics to be addressed in the near future…

Several different lattice spacings, $N \neq Z$ nuclei, adiabatic projection with hardwall boundaries for reactions, transition from S-wave to P-wave pairing in superfluid neutron matter, etc.
