# I. Introduction

One-dimensional isentropic Euler equations :

- ▶ The  $p$ -system (compressible Euler equation in Lagrangian coordinates) :

$$\begin{cases} \partial_t \tau - \partial_x v = 0, \\ \partial_t v + \partial_x (\kappa \tau^{-\gamma}) = 0. \end{cases} \quad (\text{P})$$

- ▶ In original Eulerian coordinates :

$$\begin{cases} \partial_t \rho + \partial_x m = 0, \\ \partial_t m + \partial_x \left( \frac{m^2}{\rho} + \kappa \rho^\gamma \right) = 0. \end{cases}$$

where

- ▶  $\rho = \rho(t, x) \geq 0$  is the density of the fluid,
- ▶  $m(t, x)$  is the momentum ( $v(t, x) = \frac{m(t, x)}{\rho(t, x)}$  is the velocity of the fluid),
- ▶  $\tau := 1/\rho$  is the specific volume,
- ▶ the pressure law is  $p(\rho) = \kappa \rho^\gamma$ ,  $\gamma \in (1, 3]$ .

# Controllability problem

- ▶ Domain :  $(t, x) \in [0, T] \times [0, L]$ .
- ▶ State of the system :  $u = (\tau, v)$ .
- ▶ **Control** : the “boundary data” : here, on **one** side, say  $x = 0$ , while there is a fixed **boundary law** at  $x = L$ .
- ▶ **Controllability problem** : given  $u_0$  and  $u_1$ , can we find **boundary data**  $x = 0$  driving the state from  $u_0$  to  $u_1$  ?
- ▶ **Equivalently** : given  $u_0$  and  $u_1$ , can we find **a solution** of the system satisfying the boundary condition and driving  $u_0$  to  $u_1$  ?

## Systems of conservation laws

- ▶ Both systems enter the class of **hyperbolic systems of conservation laws** :

$$U_t + f(U)_x = 0, \quad f : \Omega \subset \mathbb{R}^n \rightarrow \mathbb{R}^n, \quad (\text{SCL})$$

satisfying the (strict) hyperbolicity condition that at each point

$df$  has  $n$  distinct real eigenvalues  $\lambda_1 < \dots < \lambda_n$ .

- ▶ Hyperbolic systems of conservation laws develop **singularities in finite time**.
- ▶ This easy to see for instance for the Burgers equation :

$$u_t + (u^2)_x = 0.$$

# Class of solutions

- ▶ One can either work with **regular solutions** ( $C^1$ ) with small  $C^1$ -norm (for small time), or with **discontinuous (weak) solutions**.
- ▶ For the latter case, is natural for the sake of uniqueness to consider weak solutions which satisfy **entropy conditions** (**entropy solutions**).
- ▶ More precisely, the solutions will be of **bounded variation**, with small total variation in  $x$  (“à la Glimm”).
- ▶ Note that there exist weaker solutions (DiPerna, Lions-Perthame-Souganidis-Tadmor, etc.)

# Entropy conditions

## Definition

An **entropy/entropy flux couple** for a hyperbolic system of conservation laws (SCL) is defined as a couple of regular functions  $(\eta, q) : \Omega \rightarrow \mathbb{R}$  satisfying :

$$\forall U \in \Omega, \quad D\eta(U) \cdot Df(U) = Dq(U).$$

## Definition

A function  $U \in L^\infty(0, T; BV(0, L)) \cap \mathcal{L}ip(0, T; L^1(0, L))$  is called an **entropy solution** of (SCL) when, for any entropy/entropy flux couple  $(\eta, q)$ , with  $\eta$  **convex**, one has in the sense of measures

$$\eta(U)_t + q(U)_x \leq 0,$$

that is, for all  $\varphi \in \mathcal{D}((0, T) \times (0, L))$  with  $\varphi \geq 0$ ,

$$\int_{(0, T) \times (0, L)} (\eta(U(t, x))\varphi_t(t, x) + q(U(t, x))\varphi_x(t, x)) dx dt \geq 0.$$

## Boundary condition

- ▶ Our boundary condition will take the following form at  $x = L$  :

$$b(u(t, L)) = 0 \text{ for a.e. } t,$$

where  $b = b(\rho, v) : \mathbb{R}^+ \times \mathbb{R} \rightarrow \mathbb{R}$  is a function satisfying some **non-degeneracy conditions** (to be specified later).

- ▶ **Examples :**

- ▶  $v = 0$  : zero-speed on the right boundary,
- ▶  $\rho = \bar{\rho}$  : constant density (or constant pressure) at  $x = L$ .

# Main result

## Theorem

Let  $b$  satisfy the non-degeneracy condition.

Let  $\bar{u}_0 := (\bar{\tau}_0, \bar{v}_0) \in \mathbb{R}^2$  with  $\bar{\tau}_0 > 0$  and  $b(\bar{u}_0) = 0$  and let  $\bar{u}_1 = (\bar{\tau}_1, \bar{v}_1)$  with  $\bar{\tau}_1 > 0$  and  $b(\bar{u}_1) = 0$ .

There exist  $\varepsilon > 0$  and  $T > 0$  such that for any  $u_0 = (\tau_0, v_0)$  in  $BV(0, L; \mathbb{R}^2)$  such that

$$\|u_0 - \bar{u}_0\|_{L^\infty(0, L)} + TV(u_0) \leq \varepsilon,$$

and  $b(u_0(L^-)) = 0$ , there is

$$u \in L^\infty(0, T; BV(0, L)) \cap \mathcal{L}ip([0, T]; L^1(0, L)),$$

a weak entropy solution of the  $p$ -system such that

$$u|_{t=0} = u_0 \quad \text{and} \quad u|_{t=T} = \bar{u}_1.$$

## Refined variant

### Theorem

Let  $b$  satisfy the non-degeneracy condition.

Let  $\bar{u}_0 := (\bar{\tau}_0, \bar{v}_0) \in \mathbb{R}^2$  with  $\bar{\tau}_0 > 0$  and  $b(\bar{u}_0) = 0$  and let  $\bar{u}_1 = (\bar{\tau}_1, \bar{v}_1)$  with  $\bar{\tau}_1 > 0$  and  $b(\bar{u}_1) = 0$ .

Let  $\eta > 0$ . There exist  $\varepsilon > 0$  and  $T > 0$  such that for any  $u_0 = (\tau_0, v_0)$  in  $BV(0, L; \mathbb{R}^2)$  such that

$$\|u_0 - \bar{u}_0\|_{L^\infty(0, L)} + TV(u_0) \leq \varepsilon,$$

and  $b(u_0(L^-)) = 0$ , there is

$$u \in L^\infty(0, T; BV(0, L)) \cap \mathcal{L}ip([0, T]; L^1(0, L)),$$

a weak entropy solution of the  $p$ -system such that

$$u|_{t=0} = u_0 \quad \text{and} \quad u|_{t=T} = \bar{u}_1,$$

and

$$TV(u(t, \cdot)) \leq \eta, \quad \forall t \in (0, T).$$

## II. Two connected results

- ▶ Bressan and Coclite (2002) : for a class of systems containing Di Perna's system :

$$\begin{cases} \partial_t \rho + \partial_x(\rho u) = 0, \\ \partial_t u + \partial_x \left( \frac{u^2}{2} + \frac{\kappa^2}{\gamma-1} \rho^{\gamma-1} \right) = 0, \end{cases}$$

there are initial conditions  $\varphi \in BV([0, 1])$  of arbitrary small total variation such that any entropy solution  $u$  remaining of small total variation satisfies : for any  $t$ ,  $u(t, \cdot)$  is not constant.  $\neq C^1$  case!

- ▶ G. (2007) : A sufficient condition concerning the isentropic Euler equation

$$(E) : \begin{cases} \partial_t \rho + \partial_x(\rho u) = 0, \\ \partial_t(\rho u) + \partial_x(\rho u^2 + \kappa \rho^\gamma) = 0, \end{cases} \quad (P) : \begin{cases} \partial_t \tau - \partial_x v = 0, \\ \partial_t v + \partial_x(\kappa \tau^{-\gamma}) = 0, \end{cases}$$

for final states to be reachable. For instance, all constant states are reachable.

### III. Basic facts on systems of conservation laws

- ▶ Systems of conservation laws :

$$u_t + f(u)_x = 0, \quad f : \mathbb{R}^n \rightarrow \mathbb{R}^n,$$

$A(u) := df(u)$  has  $n$  real distinct eigenvalues  $\lambda_1 < \dots < \lambda_n$ , which are **characteristic speeds of the system** with corresponding eigenvectors  $r_i(u)$ .

- ▶ **Genuinely non-linear** fields in the sense of Lax :

$$\nabla \lambda_i \cdot r_i \neq 0 \quad \text{for all } u.$$

$\Rightarrow$  we normalize  $\nabla \lambda_i \cdot r_i = 1$ .

- ▶ In the case of (P) we have

$$\lambda_1 = -\sqrt{\kappa\gamma\tau^{-\gamma-1}} \quad \text{and} \quad \lambda_2 = \sqrt{\kappa\gamma\tau^{-\gamma-1}}.$$

## Boundary conditions

- ▶ We can now express our **non-degeneracy condition** on the boundary law  $b : \mathbb{R}^+ \times \mathbb{R} \rightarrow \mathbb{R}$ .

We ask that  $b$  satisfies the two following conditions :

- ▶ **Standard** condition for the Cauchy problem :

$$r_1 \cdot \nabla b \neq 0 \text{ on } \Omega,$$

- ▶ Condition for the **backward in time** Cauchy problem :

$$r_2 \cdot \nabla b \neq 0 \text{ on } \Omega,$$

# The Riemann problem

- ▶ Find autosimilar solutions  $u = \bar{u}(x/t)$  to

$$\begin{cases} u_t + (f(u))_x = 0 \\ u|_{\mathbb{R}^-} = u_l \text{ and } u|_{\mathbb{R}^+} = u_r. \end{cases}$$

- ▶ Solved by introducing Lax's curves which consist of points that can be joined starting from  $u_l$  either by a **shock** or a **rarefaction wave**.

# Shocks and rarefaction waves

## Shocks

Discontinuities satisfying :

- ▶ Rankine-Hugoniot (jump) relations

$$[f(u)] = s[u],$$

- ▶ Lax's inequalities :

$$\lambda_i(u_r) < s < \lambda_i(u_l)$$

Propagates at speed  $s \sim \int_{u_l}^{u_r} \lambda_i$

## Rarefaction waves

Regular solutions, obtained with integral curves of  $r_i$  :

$$\begin{cases} \frac{d}{d\sigma} R_i(\sigma) = r_i(R_i(\sigma)), \\ R_i(0) = u_l, \end{cases}$$

with  $\sigma \geq 0$ .

Propagates at speed  $\lambda_i(R_i(\sigma))$

# Solving the Riemann problem

- ▶ Lax's Theorem proves that one can solve (at least locally) the Riemann problem by first following the 1-curve (gathering states connected to  $u_l$  by a 1-rarefaction/1-shock), then the 2-curve.

# Boundary Riemann problem

- ▶ The same principle applies on the boundary (both forward and backward in time)

# Front-tracking algorithm (Dafermos, Di Perna, Bressan, Risebro, ...)

- ▶ Approximate initial condition by piecewise constant functions
- ▶ Solve the Riemann problems and replace rarefaction waves by rarefaction fans

- ▶ One obtain a piecewise constant function, with straight discontinuities (**fronts**)
- ▶ iterate the process at each **interaction point** (points where fronts meet)

## Estimates, convergence, etc.

- ▶ One shows that this defines a piecewise constant function, with a finite number of fronts and discrete interaction points.
- ▶ A central argument is due to Glimm : analyzing interactions of fronts  $\alpha + \beta \rightarrow \alpha' + \beta' + \gamma'$  and the evolution of the **strength of waves** across an interaction, one proves that :

*if  $TV(u_0)$  is small enough,  
then  $TV(u(t)) \leq C TV(u_0)$  for some  $C > 0$ .*

- ▶ One deduces bounds in  $L_t^\infty BV_x$ , then in  $\text{Lip}_t L_x^1$ , so we have compactness. . .

## IV. A light idea of the construction when the control acts on both sides

- ▶ Bressan & Coclite's counterexample. DiPerna's system is a  $2 \times 2$  hyperbolic system with GNL fields, and which satisfies

*the interaction of two shocks of the same family generates a shock in this family (normal) and a shock in the other family.*

Hence starting from an initial date with a dense set of shocks, this propagates over time, even with control on both sides.

- ▶ A basic idea (even to control on both sides) is to use the fact that for the  $p$ -system :

*the interaction of two shocks of the same family generates a shock in this family (normal) and a rarefaction in the other family.*

# Some ideas, control from both boundaries, 1

- ▶ To begin with, sends a **strong (large) shock** of the second family from the boundary.

## Some ideas, control from both boundaries, 2

- ▶ Then one sends additional 2-shocks from the boundary and one relies on cancellations to prevent 1-shocks to cross.

- ▶ To make the construction, use  $L - x$  as time variable.
- ▶ Since only 1-rarefactions cross and since they do not interact, the system reaches a constant state after a finite time.

## V. A light idea of the construction, one-side controls

- ▶ When one controls **only from one side** (say, from the left), there are two differences :
  - ▶ One has to take into account **the reflections at  $x = L$  below the strong shock**. Not an issue.
  - ▶ One has to take into account **the reflections at  $x = L$  of the strong shock**. There are two situations, one of which changes everything.
- ▶ **Situation 1.** The strong 2-shock is reflected as a **1-rarefaction** when

$$(r_1 \cdot \nabla b)(r_2 \cdot \nabla b) < 0.$$

In this case, since this adds a rarefaction to the picture, the above construction still works.

- ▶ **Situation 2.** The strong 2-shock is reflected as a **1-shock** when

$$(r_1 \cdot \nabla b)(r_2 \cdot \nabla b) > 0.$$

In this case, one needs an additional construction.

**Example** :  $v = 0$  at  $x = L$ .

# A reflection as a shock

- ▶ When the strong 2-shock is reflected as a 1-shock, it can then interact with 1-rarefactions, and one does not reach a constant state.

## A picture of the construction

- ▶ When there is a reflected strong shock, then the idea is to send again more small 2-shocks from the boundary (or here more precisely **compression fronts**) and rely on the reflection at  $x = L$  to cancel the rarefactions fronts that interact with the reflected strong 1-shock.

# Main difficulty

- ▶ There is no “good” direction of time to make the construction. Whether you use  $t$ ,  $T - t$ ,  $x$ ,  $L - x$  and so on as a time direction, the construction depends on the future.

- ▶ Hence to reach the previous picture of the construction, we rely on a fixed-point scheme.
- ▶ Problem : the front-tracking approach makes the scheme discontinuous. . .

Thank you for your attention !
