

Tensor Network Methods in 2D at Finite Temperature

Olivier Gauthé

Entanglement in Strongly Correlated Systems
Benasque

August, 16th 2023

Primer plato

- ▶ Frustrated Spin Systems at Finite Temperature in 2D

Segundo plato

- ▶ Purification and Ancilla

Postre

- ▶ METTS and XTRG

- 1 Frustrated Spin Systems at Finite Temperature in 2D
- 2 Purification and Ancilla
- 3 METTS and XTRG

Frustrated magnetism

- ▶ magnetic insulators
- ▶ competing magnetic interactions
- ▶ no classical configuration fulfilling all local constraints

- ▶ exotic physics: quantum spin liquids, residual entropy, order by disorder...
- ▶ highly relevant experimentally
- ▶ numerically challenging (sign problem)

$J_1 - J_2$ Heisenberg model

- ▶ spin-1/2 on the square lattice
- ▶ $J_1 = 1$ first neighbor interaction
- ▶ $J_2 > 0$ second neighbor: magnetic frustration
- ▶ possible spin liquid realization
- ▶ describes iron-base superconductors magnetism

$$\mathcal{H} = \sum_{\langle i,j \rangle} \mathbf{S}_i \cdot \mathbf{S}_j + J_2 \sum_{\langle\langle i,j \rangle\rangle} \mathbf{S}_i \cdot \mathbf{S}_j$$

[Chandra & Douçot, 1988]

[Ferrari & Becca, 2020]

[Liu et al., 2022]

[Nomura & Imada, 2021]

Shastry-Sutherland model

- ▶ $J_D = 1$ dimer interaction
- ▶ J' square lattice interaction
- ▶ exact dimer product ground state for small J'
- ▶ experimental realization in $\text{SrCu}_2(\text{BO}_3)_2$

$$\mathcal{H} = J_D \sum \mathbf{S}_i \cdot \mathbf{S}_j + J' \sum \mathbf{S}_i \cdot \mathbf{S}_j$$

[Shastry & Sutherland, 1981]

[Kageyama et al., 1999]

[Corboz & Mila, 2013]

Tensor description of a wavefunction

- ▶ virtual variables of dimension D
- ▶ coefficients obtained by summing over virtual variables:

$$c_{i_1 i_2 i_3 i_4} = \text{Tr} [A^{i_1} B^{i_2} C^{i_3} D^{i_4}].$$

- ▶ $D = 1$: product state (mean-field)
- ▶ virtual variables carry entanglement

Entanglement entropy and area law

Most of the Hilbert space is junk!

- ▶ reduced density matrix of subregion A :

$$\rho_A = \text{Tr}_{\bar{A}} |\Psi\rangle \langle \Psi|$$

$$S_{\text{ent}}(A) = -\text{Tr} \rho_A \ln \rho_A$$

- ▶ random state obey volume law $S_{\text{ent}}(A) \propto |A|$
- ▶ low energy states of local Hamiltonians obey **area law**:

$$S_{\text{ent}}(A) \propto |\partial A|$$

- ▶ tensor networks: $S_{\text{ent}}(A) \leq \ln D$

Tensor networks provide efficient representation of low-entanglement states!

The problem

Tensor networks provide very good ansätze for low-energy *states*.
How to construct finite temperature *density matrix*?

$$\rho(\beta) = \frac{1}{Z(\beta)} \exp(-\beta\mathcal{H})$$

3 main solutions:

- ▶ purification
- ▶ typical state sampling
- ▶ direct contraction of MPO/PEPO

sweet: can implement any continuous symmetry for 2D systems!

- 1 Frustrated Spin Systems at Finite Temperature in 2D
- 2 Purification and Ancilla
- 3 METTS and XTRG

Thermal ensemble and purification

- ▶ density matrix ρ obtained from *purified* wavefunction $|\Psi\rangle$
- ▶ $|\Psi\rangle$ lives in enlarged Hilbert space $\tilde{H} = H \otimes H'$

$$|\Psi\rangle = \sum \sqrt{p_i} |i\rangle \otimes |i'\rangle$$

- ▶ trace over auxiliary degrees of freedom to recover thermal ensemble

$$\rho(\beta) = \text{Tr}_{\text{auxiliary}} |\Psi(\beta)\rangle \langle \Psi(\beta)|$$

- ▶ use imaginary time evolution to reach thermal states

$$|\Psi(\beta)\rangle = e^{-\frac{1}{2}\beta\mathcal{H}} |\Psi(0)\rangle$$

Thermal tensor networks with ancilla

- ▶ thermal equilibrium: area law for entanglement
 - ▶ weakly entangled $|\Psi\rangle$: tensor networks ✓
 - ▶ each site described by local tensor w. ancilla
 - ▶ virtual dimension D controls approximation
-
- ▶ Matrix Product States (MPS) on the cylinder
 - ▶ 2D: Projected Entangled Pair States (PEPS)

$$\Psi_{123\dots} = \sum_{\text{virtual}} A_{abcd}^{[1]} A_{defg}^{[2]} A_{behi}^{[3]} \dots$$

[Verstraete, García-Ripoll, & Cirac, 2004]

[Verstraete & Cirac, 2004]

Purification: cooking recipe

- 1 choose tensor network geometry (MPS, PEPS)
- 2 finite or repeated unit cell
- 3 start from exact product state at $\beta = 0$
- 4 imaginary time evolve up to $\beta = 1/T$
(TEBD, TDVP, SU, NTU, FU, eeFU, ...)
- 5 trace over auxiliary variables
- 6 contract the tensor network and compute observables
(CTMRG, TRG, VUMPS, ...)
- 7 enjoy with lettuce and olive oil

Imaginary time evolution

- ▶ Trotter-Suzuki decomposition: $\exp(-\beta\mathcal{H}) \approx \prod e^{-\tau h_i}$ with small τ
 - ▶ start from $|\Psi(D)\rangle$
 - ▶ apply gate on physical legs: obtain $|\Psi'(d^2 D)\rangle$
 - ▶ renormalize tensors: find $|\Psi''(D)\rangle$ that maximizes fidelity with $|\Psi'\rangle$
-
- ▶ 2D: no optimal gauge!
 - ▶ need (approximated) metric tensor

[Czarnik & Dziarmaga, 2018]

[Czarnik, Dziarmaga, & Corboz, 2019]

Simple update

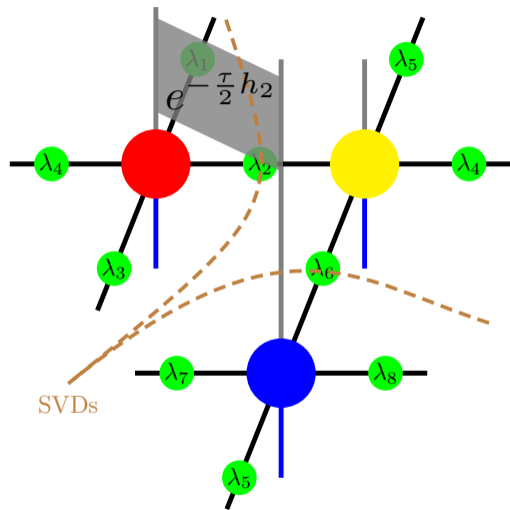

- ▶ contract only involved tensors
 - ▶ apply gate $e^{-\tau h}$
 - ▶ diagonal weights λ_b as environment
 - ▶ get new set of weights λ_b
-
- ▶ cheap
 - ▶ stable
 - ▶ automatically selects symmetry sector
 - ▶ not well controlled (short range)

[Jiang, Weng, & Xiang, 2008]

Simple update: next nearest neighbor

- ▶ similar for J_2 with intermediate site
- ▶ apply twice $e^{-\frac{\tau}{2}h_2}$ with different proxy
- ▶ C_{4v} asymmetric
- ▶ need to renormalize non-involved intermediate tensor

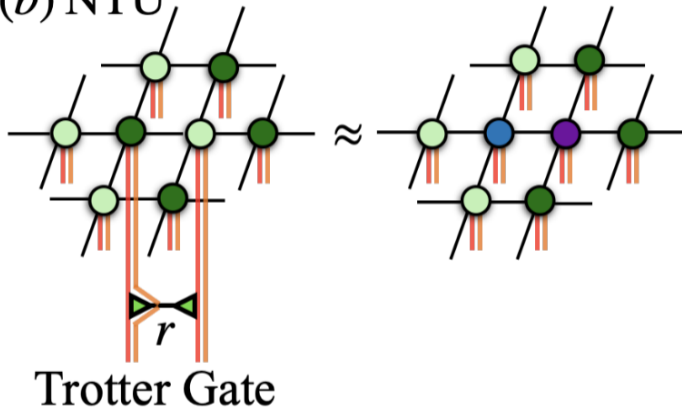

[Corboz, Jordan, & Vidal, 2010]

Neighborhood Tensor Update

- ▶ use single layer of tensor environment as metric tensor
- ▶ stable
- ▶ moderately expensive
- ▶ cost of second neighbor update?
- ▶ better than SU (still short range)

(b) NTU

[Dziarmaga, 2021]

[Sinha et al., 2022]

Full Update

- ▶ use converged environment (CTMRG...)
- ▶ rigorous and controlled
- ▶ second neighbor with intermediate sites
- ▶ extremely expensive
- ▶ instable

[Corboz et al., 2010]

[Phien et al., 2015]

Corner Transfer Matrix Renormalization Group

- ▶ 2D: contraction is hard
- ▶ define bilayer tensor
- ▶ construct environment tensors
- ▶ corner dimension χ *controls* approximation
- ▶ most expensive part: $O(D^{12})$
- ▶ other algorithms: TRG, iTEBD, VUMPS

Work directly in the thermodynamic limit!

[Nishino & Okunishi, 1996]

[Orús & Vidal, 2009]

[Corboz et al., 2011]

Benchmark: High Temperature Series Expansion

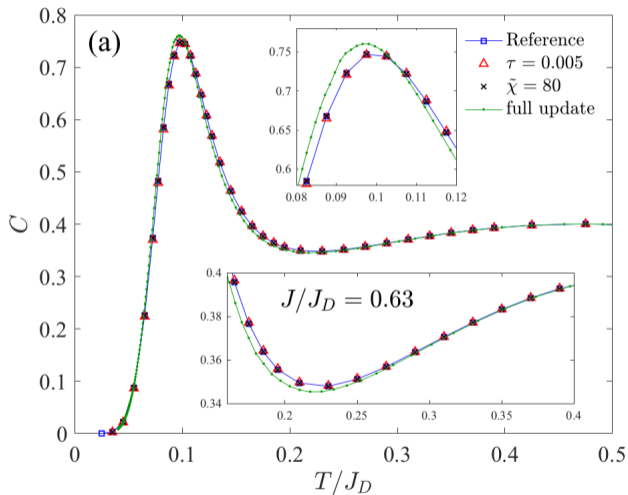

- ▶ $J_1 - J_2$ model with $J_2 = 0.50$
- ▶ Padé approximant for lower temperature
- ▶ perfect agreement at high temperature

[Rosner et al., 2003]

Benchmark: SU and FU

- ▶ Shastry Sutherland model
- ▶ dimer phase
- ▶ surprisingly good performances with SU

[Wietek et al., 2019]

Critical point in the Shastry-Sutherland

- ▶ First order transition between dimer and plaquette phases
- ▶ Finite temperature: first order line and critical point
- ▶ Experimentally observed in $\text{SrCu}_2(\text{BO}_3)_2$!

[Jiménez et al., 2021]

Finite temperature phase transition in the $J_1 - J_2$

- ▶ Mermin–Wagner: $SU(2)$ symmetry cannot be broken at $T > 0$
- ▶ finite temperature Ising transition

- ▶ stripe direction selected *before* Néel order appears
- ▶ spontaneous \mathbb{Z}_2 symmetry breaking
- ▶ Ising transition in Heisenberg magnet

[Chandra, Coleman, & Larkin, 1990]

Energy, specific heat and order parameter

$J_2 = 0.85 \quad D = 16$

► $C = \partial E / \partial T$

$\alpha = 0$

► $\sigma = \sum_{\langle i,j \rangle} \langle \mathbf{S}_i \cdot \mathbf{S}_j \rangle - \sum_{\langle i,j \rangle} \langle \mathbf{S}_i \cdot \mathbf{S}_j \rangle_{0.540}$

$\beta = 1/8$

[Gauthé & Mila, 2022]

Correlation lengths

- ▶ compute transfer matrix spectrum
- ▶ define $\xi_i = -1/\ln(|\lambda_i/\lambda_0|)$
- ▶ multiplet decomposition
- ▶ leading singlet: $\nu = 1$

$$J_2 = 0.85 \quad D = 16 \quad \chi = 256$$

teaser: ferro $J_1 - J_2$

- ▶ $J_1 - J_2$ with ferromagnetic $J_1 < 0$
- ▶ difficulties to directly probe first order transition

See my poster!

Any drawback?

- ▶ iPEPS is very expensive
- ▶ converging the environment sometimes fails
- ▶ D extrapolation is complicate

Any drawback?

- ▶ iPEPS is very expensive
- ▶ converging the environment sometimes fails
- ▶ D extrapolation is complicate
- ▶ **results can be totally wrong**

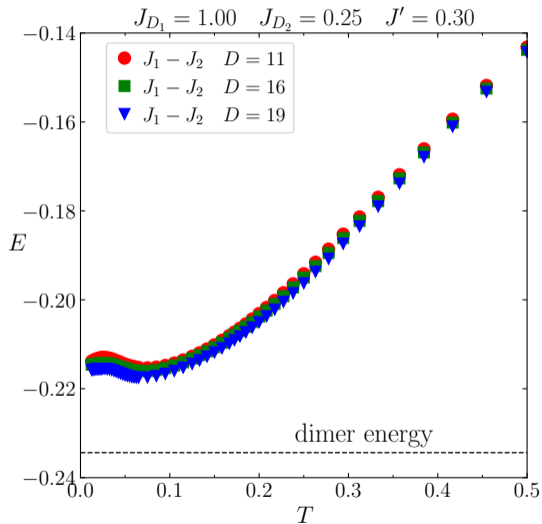

Problem: reaching low temperature

- ▶ energy rises at low T
- ▶ end of validity
- ▶ link with problem for Lorentzian PEPS?
- ▶ prevents any D scaling

Problem: results validity

- ▶ asymmetric Shastry-Sutherland
- ▶ $J_{D_1} \neq J_{D_2}$
- ▶ D looks converged
- ▶ cannot find dimer ground state

Different PEPS setups

$J_1 - J_2$ setup

1 tensor = 1 site
 $d = 2$
favors Néel

- ▶ $T = 0$: energy can be compared
- ▶ finite temperature: uncontrolled bias

dimer setup

1 tensor = 2 sites
 $d = 4$
favors dimers

plaquette setup

1 tensor = 4 sites
 $d = 16$
favors plaquettes

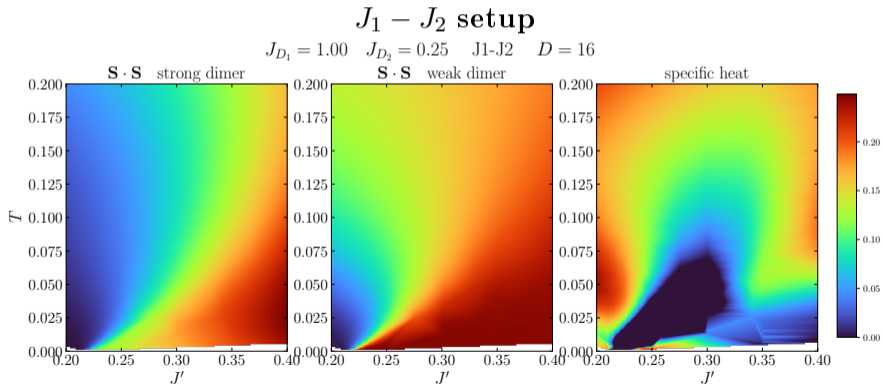

Setup effects

- ▶ $J_1 - J_2$ setup imposes Néel like correlations
- ▶ the *phase* was wrong
- ▶ dimer setup is correct
- ▶ $\xi < 2$ here!

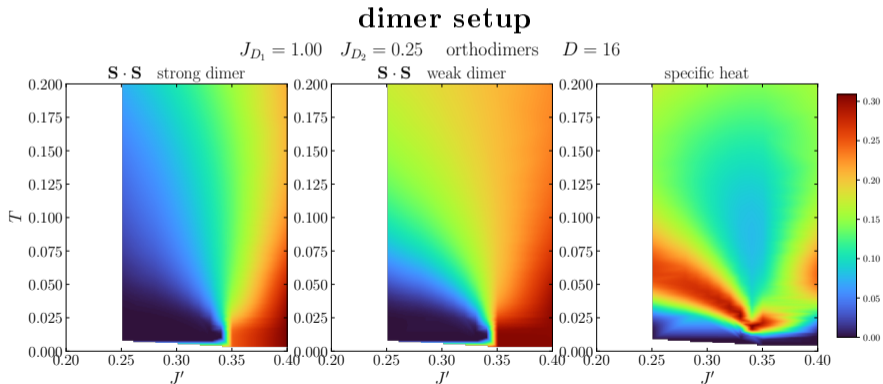

Setup effects: $J_1 - J_2$ for Shastry-Sutherland

- ▶ asymmetric Shastry-Sutherland
- ▶ $J_{D_1} \neq J_{D_2}$
- ▶ specific heat is negative

Setup effects: dimers for Shastry-Sutherland

- ▶ asymmetric Shastry-Sutherland
- ▶ $J_{D_1} \neq J_{D_2}$
- ▶ clean critical point

Conclusion on purification

- ▶ nearly exact at high temperature
- ▶ probes critical points and second order transition
- ▶ first order transition harder but possible

- ▶ hard to reach very low temperatures
- ▶ highly setup dependent: effect stronger than finite D
- ▶ requires knowledge of zero temperature phase
- ▶ problem when phase boundary matches setup validity

- 1 Frustrated Spin Systems at Finite Temperature in 2D
- 2 Purification and Ancilla
- 3 METTS and XTRG**

- ▶ many-body Hilbert space is huge
- ▶ a random state is typical with probability 1 for large systems

$$Z(\beta) = \sum_i \langle i | e^{-\beta H} | i \rangle$$

- ▶ sample states instead of full computation (TPQ)
- ▶ how to deal with entanglement?

Minimally Entangled Typical Thermal States

- ▶ idea: use classical product state as sampling basis
- ▶ describe pure state as a MPS
- ▶ no purification needed: gain factor d for each tensor!
- ▶ able to reach very low temperature
- ▶ currently cylinder MPS method (see Aritra Sinha's talk for 2D)
- ▶ finite size systems

[Stoudenmire & White, 2010]

[Wietek et al., 2021]

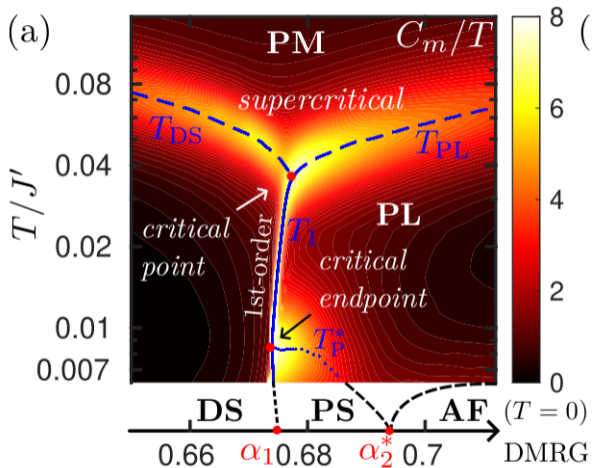

- ▶ start from random product state
- ▶ imaginary time evolve MPS up to β
 - ▶ compute observables
- ▶ project back to classical product state
 - ▶ collapse each site at a time with probability given by overlap
 - ▶ choose maximally mixed basis every other step
- ▶ iterate Markov process

- ▶ construct an MPO for $e^{-\tau H}$ with series expansion
- ▶ square the MPO: double τ
- ▶ renormalize MPO bond dimension
- ▶ reach exponentially fast any β
- ▶ cylinder MPS
- ▶ 2D generalization not straightforward

[Chen et al., 2018]

Second order transition in the Shastry-Sutherland

- ▶ plaquettes appear at finite temperature
- ▶ lattice symmetry breaking
- ▶ extremely low temperature: $\beta > 100$
- ▶ $W = 6 \quad L = 4W$

[Wang et al., 2023]

Conclusion

- ▶ tensor networks are a powerful tool to simulate finite temperatures
- ▶ methodological developments still needed
- ▶ purification is best at high temperature
- ▶ only naturally 2D method
- ▶ setup may lead to incorrect phase
- ▶ METTS and XTRG in 2D?

Thank you for your attention!

Problem: results validity

- ▶ $J_1 - J_2$ model on the checkerboard lattice
- ▶ $D = 16$ is off
- ▶ $D \geq 19$ effects still strong

Setup effects

- ▶ $J_1 - J_2$ setup imposes Néel like correlations
- ▶ the *phase* was wrong
- ▶ $\xi < 2$ here!
- ▶ plaquette setup looks correct
